The history of preventive medicine in the tropics so far as the British possessions are concerned is similar to that of Great Britain but differs in being many chapters behind. To a limited extent the practice of preventive medicine in the tropics has been based on the results of general observations and experience on the spot guided by the tenets which have held sway in England, the underlying principle of which is that cleanliness in its widest sense is the chief sanitary law. It is a good foundation to work upon and if later discoveries show that it does not cover the whole field of preventive medicine there can be little doubt it includes a very large portion. Before Pasteur's work revealed to us the process and meaning of putrefaction and fermentation and led to those epoch-making discoveries which resulted in the recognition of many of the bacterial agents of disease, the sanitarians of the time held that the best way to secure the well-being of the community and freedom from disease was the practice of measures having for their aim the purity of air, water, food, and environment. The success which attended action based on this principle is written large in the records of the great changes and improvements in the healthiness of localities [illegible] man's grave." [illegible] nce when the [illegible] the domain of [illegible] d some of the [illegible] es. They are [illegible] army and the army surgeon, the latter of whom in the early days of colonial enterprise and expansion had charge of the troops and of the small white population who formed the vanguard of that large body of our countrymen who now spend so much of their lives in our great tropical colonies and dependencies. In the early days of our occupation of the West Indies, fever, scorbutic dysentery, and phthisis played such havoc with the troops that it was estimated that the lifetime of a regiment 1000 strong was about five years. This mortality was at first attributed to the climate until experience showed it to be due to removable causes. It occurred under the following conditions. The food of the soldiers consisted mainly of salted meat with but a scanty supply of fresh vegetables, the drinking water was taken from polluted sources, the barracks were built on unhealthy sites and were ill-constructed, they were without adequate ventilation and were overcrowded, the cubic space for each man being about 250 feet. The sanitary arrangements were foul and often of the most primitive character. These conditions, associated with a want of knowledge as to the necessity of adapting the customs followed in a cold climate in regard to food, drink, dress, and exercise to those most suited for a tropical country, accounted in a large degree for the deplorable state of ill-health. The mortality for Europeans in the 20 years from 1817 to 1836 was in Jamaica 121 per 1000, in Trinidad 106, in Barbadoes 55, and in St. Lucia 122. When the conditions mentioned were improved a steady decline took place in the death-rate. In India the death-rate of the soldier has also fallen from 80 per 1000 to 16 per 1000. A marked decrease in mortality has also occurred among the civil population in a few of the principal towns of India owing largely to a greater freedom from cholera and fever brought about by the introduction of pure water-supplies, good drainage, and supervision of the sanitary arrangements by specially appointed medical officers. There has also been a great decline in the death-rate of European officials in the west coast of Africa, which in the early part of last century was worse than that in the West Indies, and there can be little doubt that, with a continuance of the policy lately introduced by Sir Matthew Nathan and Sir William McGregor, there will be further improvement.

That is one aspect of preventive medicine in the tropics and a very pleasing aspect it is as far as it goes. It shows what can be accomplished in special communities by sanitary organisation and administration and it is an indication of that which can be done on a much larger scale. The next step is that the work which has been so beneficial to a few individuals and to special communities shall be extended on [illegible] use of the discoveries which have been made from time to time by the pursuit of researches in the laboratory by experimental work, by epidemiological inquiries, and by investigation into outbreaks. Each of these methods in its own way advances our knowledge concerning the causation of disease. To-day laboratory methods are more in the foreground than the others, and at the present moment deservedly so because of the conspicuous successes which have followed activity in this particular line of research.

It is not surprising that the microscope and the laboratory should hold the position they do in tropical medicine, for the advances achieved by workers making use of them are little short of marvellous. I need only bring to your memory the discovery of the cholera bacillus by Koch; of the malarial parasite by Laveran and of its life cycle in the mosquito by Manson and Ross; of the micrococcus of Malta fever by Bruce; of the trypanosome of sleeping sickness by Castellani and Bruce; of filaria by Lewis and its life history by Manson; of the plague bacillus by Kitasato and Yersin; of the Leishman-Donovan bodies by Leishman and Donovan found in cases diagnosed as malarial cachexia with enlarged spleen and which differentiates one of those unclassified fevers which Crombie drew attention to some years ago. Then there are the numerous discoveries connected with ankylostomiasis, bilharzia, guinea worm, and other tropical diseases. This incomplete list represents achievements of the highest order which it may be taken for granted are but forerunners of further successes. With such brilliant *results there is no chance of this side of preventive* medicine languishing, except so far as it needs money and organisation for its further development. That such developments are needed is patent on every side, for we are very far from knowing all that can be learnt from laboratory methods in any of these diseases and there are hosts of other diseases still to be studied. But while appreciation of this line of research cannot be too great it must not be forgotten that the modes by which some of the most important epidemic diseases spread and the general laws which they follow were ascertained by field work as distinguished from laboratory work and before the causal agent or microbe of these diseases was discovered. I need only refer to cholera, typhoid fever, and dysentery, whose relations to contaminated water were so fully established by other than laboratory methods and which led to great practical reforms. Each method has its particular function and the true position of laboratory work is as a part of preventive medicine but not the whole. Progress will best be secured by making use of all the methods available and by bringing into practical use the knowledge which they furnish us with.

Next in rank to the discoveries of Jenner, Pasteur, and Lister I place those of Ross and Manson founded on that of Lister. To my mind the discoveries connected with malaria mark as great an epoch in the history of preventive medicine as those of Pasteur at an earlier date in that they deal with a disease which is universal in the tropics and they open a new field of research which is likely to throw light on a similar class of diseases. All our former ideas on the

No. 4226.

have always shown interest in the welfare of those under their charge, but whose difficulty, no doubt, at first will be ways and means. It is not in West Africa alone, however, that we need such a service. We need, as I stated in my address at Aberdeen in 1900, an imperial or colonial sanitary service. Towards the furtherance of a sanitary service of this kind the establishment of the schools of tropical medicine and hygiene in London was the first step. It renders the creation of such a service possible. With the necessary adjustment for local circumstances a sanitary organisation should be extended to all our tropical colonies that are in an advanced and settled condition. If this organisation were supplemented at the Colonial Office by an advisory board having the present distinguished medical adviser as its president, whose duties would be to read the sanitary reports and advise the Government on the many problems which arise in connexion with health matters, we should be on a fair way to being in a position to apply in a systematic and scientific manner practical measures based on the discoveries in malaria and other tropical diseases to their prevention.

ABSTRACT OF

A Clinical Lecture

ON

THE DIAGNOSIS OF OSTEO-SARCOMA OF THE LONG BONES.

Delivered at St. Thomas's Hospital on June 16th, 1904,

By WILLIAM H. BATTLE, F.R.C.S. Eng.,
SURGEON TO ST. THOMAS'S HOSPITAL.

GENTLEMEN,—We have recently been considering the subject of osteo-sarcoma in the wards owing to the presence in the Beatrice Ward of a patient with a hard tumour of the ilium of rapid growth. It is, however, most frequently in connexion with the femur that such growths are found and in the thigh there are difficulties in the diagnosis which are worth presenting to you. You will have no difficulty in making a diagnosis in cases of ordinary exostosis, ossification of tendons, or ossification of tendons near a Charcot's joint. Central myeloid growths with their thin coating of expanded bone are usually easy to comprehend and I do not refer to them but to the sarcomatous growths, mostly peripheral in origin, in which bony tissue has developed and which have attained a large size when they present themselves for treatment. As a rule, in such cases we get an account of a tumour of rapid painless growth, with, or perhaps without, a history of injury. The tumour is hard, without tenderness, and has a well-defined, somewhat abrupt margin. An x-ray photograph probably shows an invasion of the new growth by spicules and irregular columns of new bone which radiate from the periosteum almost to the periphery of the growth. Should this arrangement of permeating bone be different and the amount of softer growth of the periphery almost imperceptible then difficulty arises, especially if there is a clear history not only of injury but of actual fracture of the bone. Of this fact the case of the patient who was shown by me at the Medical Society of London in 1901 is a good example and a photograph of the limb is reproduced in the Transactions of the Medical Society of London for that year (Fig. 1). Part of the tumour can be seen in the prepared specimen before you which resembles in section the appearance of the skiagram reproduced (Fig. 2).

The patient was a boy, aged three years and nine months, sent to me by Mr. F. W. Waters of Sheerness, and admitted for a swelling of the thigh into Leopold Ward. St. Thomas's Hospital, on Nov. 8th, 1901. The following is from notes by Mr. G. T. Birks. There was no family history of tumours. (The mother of the boy developed sarcoma of the thigh and underwent amputation at another hospital some months after the boy had undergone amputation for his tumour.) It appears that on April 1st the patient fell and broke his left thigh. He was taken to a medical man three days later and the limb was put in a plaster-of-Paris splint. Three weeks later the splint had to be removed on account of the increased size of the thigh. Sand-bags were then employed for two weeks to keep the limb at rest. His mother said that the affected thigh had at one time measured 25 inches in circumference but was now diminishing. He was in no way out of health at the time of the accident or afterwards.

On admission the state was as follows. "The left thigh exhibits a smooth, somewhat fusiform enlargement extending from the knee to the hip. The greatest circumference of the left thigh is 14 inches, that of the right thigh is 7½ inches. The swelling is very smooth and of bony hardness and there is not a great deal of tissue intervening between it and the skin. Both above and below there is a very distinct raised outline to be felt on deep pressure. This enlargement extends all round the femur. The left leg cannot be flexed to a right angle owing to the projection of the tumour posteriorly. There is no limitation of movement at the upper end and no enlarged glands in the groin (Fig. 1). The boy appears remarkably healthy, cheerful, and free from pain, being able to run about without apparent difficulty, and there are no secondary growths to be felt. He sleeps well. The urine is normal." A skiagram showed that the whole shaft of the femur was involved in the growth, which had a very definite bony outline, whilst the substance of the tumour was traversed by a network of wavy bony lines which did not radiate from the shaft of the femur. There had been a fracture of the middle of the shaft. Some days later the tumour was again examined with the x rays and its upper limits were clearly defined, whilst the whole skeleton was searched for evidence of secondary growth but none was found. On Dec. 13th the limb was amputated at the hip-joint. The abdominal aorta was compressed by the finger of an assistant, an Esmarch's bandage was applied up to the knee, and the limb was removed after the formation of skin flaps and division of the muscles close to the pelvis. During the operation normal saline solution was injected into the subcutaneous tissue of the arm as the veins were too small to be used. The limbs were wrapped in flannel bandages and other precautions were taken against shock. Union took place by first intention and he left for home on Jan. 18th, 1902.

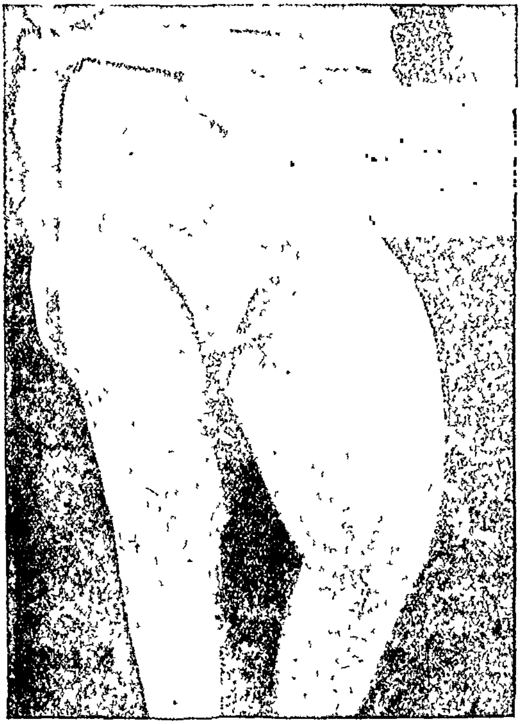
A few days before leaving a swelling was found about the upper end of the left ulna; this did not, however, develop, but in 1903 the patient returned to the hospital with a rounded growth of the lower end of the right femur, similar in feel and in appearance under the x rays to the tumour of the thigh which had been removed by amputation. No operation was recommended. His general health continued good.

This tumour had not quite the usual feel of an osteo-sarcoma of the femur, for there was apparently nothing but bone, and one suggestion offered at the meeting of the Medical Society was that it was simply a large mass of callus developed after a fracture of the femur, associated with an extensive blood extravasation. I was not able to accept this suggestion, although the bone arrangement as shown by the x rays was unusual, for it appeared to me that the upper limit of the swelling was too abrupt and the swelling too large for anything but a sarcomatous growth. A swelling produced by callus should have subsided to a much greater extent, considering the time that had elapsed since the injury, and have been of a more marked spindle shape.

A case to which I alluded at the discussion on this patient at the Medical Society, in which a woman suffered a spontaneous fracture of the femur and in whom an extensive deposit of callus followed resembling a sarcomatous growth, was that of a married woman, aged 35 years, who was admitted to the Elizabeth Ward on May 16th, 1900, with the following history (from notes by Mr. Sampson). On March 2nd of that year the patient, who had alighted from a tramcar, was walking across the road to the pavement when she suddenly felt severe pain in the left hip and became unable to walk or even to put her foot to the ground. She was conveyed home and the medical man who was called in told her that she had broken her hip. She was in bed for seven weeks; she noticed that her hip and knee both became swollen and that discolouration showed about both joints. She had pain until a week before admission and when it ceased she got up. She then discovered that the left leg was shorter than the right and that it gave her much pain to put the foot to the ground. Since March she had been losing weight. She had complained of pain in the leg for about two years before the accident but had had no difficulty in walking and noticed no difference in the length of the limbs There was no history of syphilis

On admission the following notes were made "She is a fairly well nourished woman with a large swelling of the left thigh This is hard to the touch, somewhat irregular in outline, evidently attached to the bone Chiefly prominent on the outer side of the thigh it extends over the upper third of the bone, *it is not very tender on* examination There is about an inch shortening The great trochanter of the femur appears displaced upwards but it is difficult to make certain of this as there is so much swelling in this part The hip joint does not appear to be affected but there are wasting and some weakness of the left thigh The reflexes are absent in both knees, the ankle and patellar clonus are also absent. The eyes are normal. Condition generally good The temperature is normal" A skiagram taken on May 12th showed that "there had been an old fracture of the femur about two inches below the great trochanter. The upper fragment is abducted, causing the angle formed by the neck and major part of shaft to approach a right angle" Extension applied to the thigh appeared to give relief to the pain and the patient thought it increased the length of the limb This was doubtful

FIG 1.



Osteo sarcoma of the femur in a boy aged three years and nine months which followed a fracture

The patient remained under observation in the hospital until July 7th and the swelling diminished in size After leaving the hospital she attended as an out-patient for about 12 months At the end of that time she was without pain and walked very well but the swelling had not altogether subsided

The history of this case—a spontaneous fracture followed by shortening and a tumour—made the suggestion of sarcoma a very plausible one (indeed, the case is so described to this day in the Hospital Reports) and was confirmed by the size of the tumour, which was large. Against this view were the fact that the lower margin of the growth appeared to shade off gradually, so far as could be felt, for the patient was rather fat, and the fact that the fracture had consolidated, whilst the absence of reflexes hinted at another reason for spontaneous fracture—locomotor ataxy. It was decided, therefore, to watch the case and the result *proved the wisdom of such a course*

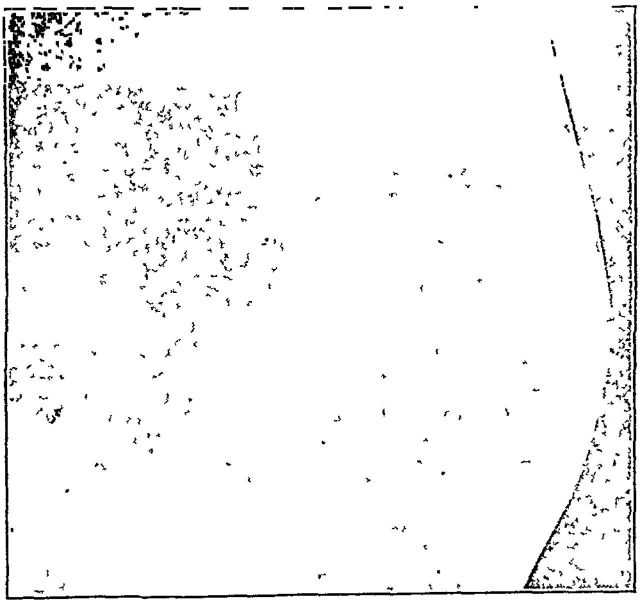
Another case in which there was a history of fracture followed by tumour, deformity, and shortening suggested still more strongly the presence of an osteo sarcoma A married woman, aged 51 years, was admitted to Beatrice Ward on Nov 26th, 1902, for a tumour of the right thigh (The following is from notes by Mr C Thompson.) The history which she first gave was that of a fall during the first week in October, she slipped on some whitewash and was unable to get up again owing to extreme pain in the right thigh She was taken to the Cottage Hospital of her part and was there treated with a long outside splint for five weeks When the splint was removed the patient says that the leg was quite straight and that it had become out of shape since It was ascertained later that she had been wearing a high boot on that side for two years before the accident She also admitted in cross examination that she had felt her right thigh bone very distinctly in the upper part during the previous July There had been occasional pain and swelling in the right knee for four years On examination of the right lower extremity it was found to be extremely rotated inwards, the inner side of the right knee lying on the bed There was also some slight adduction of the limb. In the upper and front part of the thigh there was a large prominent swelling which was of bony consistence, Nélaton's line ran through the top of this swelling which gradually shaded into the substance of the femur and this bone appeared thickened almost to the knee The patient was able to move the limb, but movement was slight and mainly in the direction of flexion, passive movement could be carried out to a similar extent and did not affect the ilium At the back of the tumour and connected with it was a smooth rounded lump which felt like the head of the femur. The right leg measured 31 inches and the left 33½ inches The family history was good and she was said to have been always healthy Menstruation had been profuse every fortnight for the last six years and she said that she had lost a good deal of blood, there had also been an offensive discharge Dr W W H. Tate kindly examined the patient and reported that the uterus was normal. The head was normal, there was no enlargement to be felt in any other bone, and no tumour could be discovered excepting that of the right thigh. The urine was of specific gravity 1020, was acid, and contained a trace of albumin. An examination with the x rays showed, early in December, that the head of the femur was lying in its normal position and that there had been a fracture of the neck A skiagram taken on Dec. 12th showed the condition which is illustrated (see Fig 2), there being great deformity about the upper end of the femur. Skiagrams taken later of the lower end of the femur and upper end of the tibia showed a woolly outline of the bones with evidence of rarefaction of the cancellous tissue

On Jan 23rd an exploratory operation was performed in the upper and outer part of the femur. A portion of the bone was removed with the trephine and sent to the Clinical [illegible] that its examination [illegible] perature was normal [illegible]ture was given. The patient declined further treatment and left the hospital on Feb 18th, 1903 The limb was quite useless and extension applied to the leg had produced no apparent effect.

This was then a case of osteitis deformans affecting the femur only, so far as could be ascertained by ordinary examination aided by the history; later the x rays showed the characteristic change in that bone and changes in the *tibia also. But at first, as there was no alteration in the* skull or elsewhere in the skeleton, the diagnosis was not clear and other things had to be considered. The helpless appearance of the limb, with the history of uterine hæmorrhage and discharge, suggested secondary carcinoma but the more complete history and the result of Dr. Tate's examination negatived this. This history and the x-ray examination made it evident that the primary condition was osteitis deformans, but the statement of recent increase in growth made it advisable to explore in order that all fear of sarcoma might be excluded; so many cases of osteitis deformans have developed a sarcomatous change and ended fatally.

Osteitis deformans rarely affects the femur only (there are usually other bones affected, including the skull) and when it does it leads to tumour of slow growth with shortening in the length of the limb. The tumour shades into the bone above and below, whilst the shortening is slowly progressive yet the patient is not prevented from going about at any time. I exhibited a patient at the Medical Society of London (see Fig. 3) with a tumour due to this disease affecting the left femur, in whom there were two inches shortening and a posterior curve, but this had been gradual and not attended with pain. Mr. A. A. Bowlby has recorded a similar case.

FIG. 2.

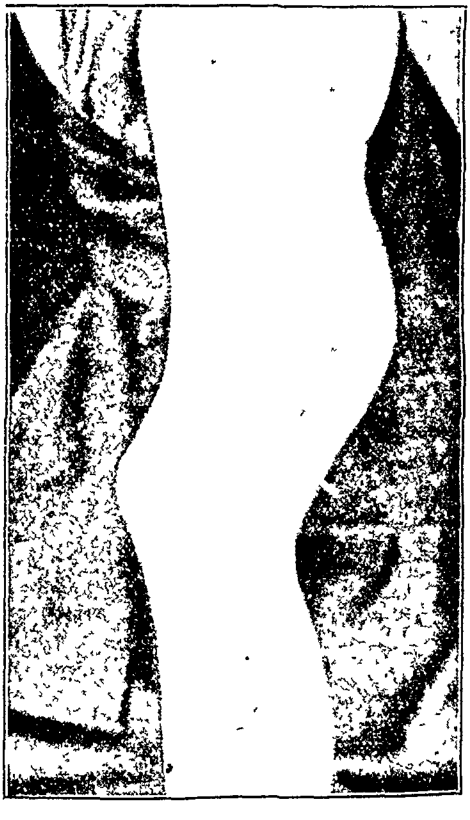


Osteitis deformans affecting the right femur in which there had also been fracture.

Quiet necrosis is one of the diseases which may very closely simulate the formation of a sarcoma of the bones and there have been several cases published since attention was drawn to it by Sir James Paget in his clinical lectures. There will have been a history of the formation of a tumour attended with little or no pain, and not only with no signs of suppuration but not even with those of inflammation. Moreover, there may have been a spontaneous fracture. In reading most of the histories of these cases one had not gathered the impression that they were likely to affect a large extent of bone, and that several inches of such a large bone as the femur could not only die but become separated without any of the signs associated with such a necrosis seemed unlikely and difficult of belief.

Some of you may recollect the following case. On Feb. 11th, 1901, a man, aged 21 years, was admitted to Leopold Ward with a tumour of the right thigh. (The following is from notes by Mr. Gibson and Mr. Raby). It was stated that his father had died from consumption but that he had enjoyed good health. He had rheumatism in October and noticed a pain in his right knee; he went to work for a day or two but then became so bad that he went to bed. He was given iodine to paint the knee, but this did it no good and the swelling became larger. There was not much pain at the time of admission and he slept fairly well, but he had become much thinner. The patient was pale, thin youth, with marked enlargement of the right thigh. The right knee appeared to be swollen but there was no effusion in the joint. Above the joint the skin was normal and the swelling extended for two-thirds of the length of the femur, encircling the bone; it was uniformly hard and fixed. No fluctuation or egg-shell crackling could be felt, but it was thought to be œdematous laterally near the knee. It was slightly tender to the touch, but at no point was this more marked than elsewhere. In circumference the right thigh at its most prominent part (the middle) measured 17½ inches and the left at a similar point 14 inches. The hip- and knee-joints were unaffected. Along the line of Poupart's ligament were several enlarged and hard glands. There was no swelling in the pelvis or sign of secondary growth or abnormal enlargement of the skeleton. The temperature was 100° F. on the night of admission, did not exceed this later, either before or after operation, and was usually normal. The liver margin extended for a distance of one inch below the costal margin, but gave no evidence of disease. The urine was of specific gravity 1020 and was acid. Albumin was present in some quantity. There was no blood. The late Dr. Blacker examined the limb with the x rays and reported as follows: "Right femur shows new bone, apparently periosteal, along the shaft of the bone. No definite sign of new growth from any particular part. ? Sequestrum in centre of shaft, the shadow being rather pronounced." On Feb. 26th a small area of fluctuation was found about four inches above the knee, but without increase of pain or tenderness (Fig. 4).

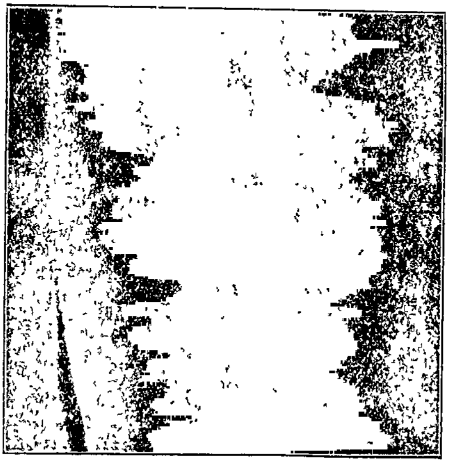
FIG. 3.



Tumour of the thigh produced by osteo arthritis with posterior excurvation.

On March 8th operation was performed under anæsthesia, an Esmarch's bandage being put high up on the thigh. An incision of six inches in length was made on the outer side above the external condyle. The muscular tissue cut almost like new growth; the bony tissue was vascular, of recent deposit, and when cut through with a chisel was found to inclose a large sequestrum. There were several smaller ones but this one extended for five or six inches upwards and included nearly the whole of the thickness of the shaft.[1] After extension of the incision and a further enlargement of the opening in the involucrum the sequestrum [illegible] considerable amount of granula- [illegible] dead bone; but no pus was seen. [illegible] was a flow of whitish fluid almost like milk from the area of fluctuation noted on Feb. 26th. The granulation tissue was examined microscopically but showed no sign of any tumour formation or of tubercle.

FIG. 4.



Quiet necrosis of femur.

The sinuses had healed before the patient left the hospital on April 24th, 1901, and the albuminuria was less. When seen some weeks afterwards he was much improved in every respect and had but a slight amount of albumin in the urine.

On admission this swelling resembled very closely that produced by an osteo-sarcoma of the femur. The absence of pain, the large extent of femur involved, a normal temperature, the presence of enlarged glands, the history of loss of flesh, and the anæmic appearance of the boy all pointed to the diagnosis of osteo-sarcoma

In favour of quiet necrosis was the feel of the upper limit of the growth which was not clearly defined but faded gradually on the femur, and the presence of œdema of the lower part (not noticed by all), and later an area of fluctuation. Œdema of the subcutaneous tissue is in favour of some change of inflammatory character, but a point of fluctuation such as that found might simply indicate a cystic change or local hæmorrhage in the case of a growth. The albuminuria must, I think, be included amongst the evidence in favour of quiet necrosis, for it diminished greatly when the wound had healed and the process of disease had been arrested. I do not think that it has been noticed in quiet necrosis hitherto, but as it may result from dry caries of the spine there appears no reason why it should not follow a dry necrosis of one of the long bones and be, as here, an indication of amyloid change in the kidneys. A normal temperature is given as in favour of sarcoma, but the course of some of the rapidly growing sarcomata is accompanied by fever—100°, 102°, 103·6°—without local signs of inflammation. This must be remembered, for a grave condition is likely immediately to ensue should an incision be made into a sarcoma under the impression that it is an abscess. I recollect one case in which this was done by a medical man before sending his patient to the hospital. The hæmorrhage was so profuse that he thought he must have opened the femoral artery. In that case redness was also present and the only guides were the long history of the case and amount of surrounding growth infiltration.

The examination by the x rays in our patient showed the exact condition; without it we might have been compelled to explore in order to make a diagnosis. Yet, as a small piece of necrosed bone might escape detection by this method, careful exploration should be made before amputation in all cases.

NOTE ON THE SERUM TREATMENT OF EXOPHTHALMIC GOITRE.

BY GEORGE R. MURRAY, M.A., M.D. CANTAB., F.R.C.P. LOND.,
HEATH PROFESSOR OF COMPARATIVE PATHOLOGY IN THE UNIVERSITY OF DURHAM, PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE.

THE treatment of exophthalmic goitre still leaves much to be desired, for although good results are obtained in many cases by our present methods improvement is often slow and some cases do badly. More especially do we require some efficient means of treating those cases in which the symptoms rapidly become acute and the patient dies within a few days. It has been my misfortune to see several of these cases where the patients have died after a few days of acute illness and it has seemed possible that in this class of case, in which the symptoms are evidently due to a toxæmia, an antitoxic serum might be useful. The evidence we at present possess tends to show that the symptoms of this malady are due to the morbid condition of the thyroid gland and are the result of an excessive formation and absorption of thyroidal secretion. Whether this secretion is simply increased in amount, while it retains the same physiological properties as in health, or is changed in constitution is still an open question which, however, may have an important bearing on the preparation of an antitoxic serum. Assuming, in the absence of proof to the contrary, that the excessive thyroidal secretion has similar physiological properties to that which is formed by the normal gland, there are different ways in which serum treatment might be of service. Thus, a cytotoxic serum prepared in the manner described by Portis might have a specific action in inducing atrophic changes in the redundant secretory epithelium of the enlarged thyroid gland and so diminish its over-activity; or an antitoxic serum might be prepared by Moebius's method or by the method adopted by Lepine and by myself, which would directly neutralise the action of the excess of secretion in the blood. We may regard the symptoms as being due to a toxæmia the source of which is the diseased thyroid gland, just as much as the toxæmia of diphtheria or tetanus is due to the production of toxins in the locally infected area; and although we have no reason to regard Graves's disease as infective in origin I see no good reason why an antitoxic serum should not be obtainable by suitable methods similar to those employed in the case of the infective diseases.

Portis[1] endeavoured to produce symptoms similar to those which follow removal of the thyroid and parathyroid glands in animals by means of specific cytotoxins selective in action on the thyroid and parathyroid cells, causing their degeneration and loss of function. The possibility of this had previously been indicated by the preliminary reports of Mankovsky[2] and of Goutscharukov,[3] both of whom had stated that they had produced thyrotoxic sera, injections of which produced symptoms like those of tetany, the thyroid cells showing evidences of degeneration. Mankovsky introduced the thyroid glands of dogs into the peritoneal cavity of cats at intervals of a fortnight and after the third injection bled the cats and separated the serum which proved toxic to dogs. Goutscharukov also used the thyroids of dogs, injecting them into rams and so produced a serum which he considered to be thyrotoxic. Portis employed increasing doses of an emulsion of dog's thyroid. Beginning with one gland he increased the dose up to ten glands, injecting the emulsion into the peritoneal cavity of a goat, not more than one month being allowed to elapse between impair the prospect of union, I believe we may confidently offer to our patients by this operation great relief from their sufferings and a measure of health undreamt of before. I will first turn to the consideration of the cases of perforated gastric ulcer.

CASE 1. *Perforated gastric ulcer, occurring twice in a year, the second operation accompanied by gastro-enterostomy.*—The patient was a female, aged 22 years. The first perforation occurred on May 17th, 1903. There was a history of gastric pain and vomiting over several years. She had been under my care for the previous 12 months. On the afternoon of May 17th whilst asleep in a chair somebody entered the room hastily and gave her a fright. This was immediately followed by sudden acute pain in the abdomen. She was first seen at 5 P.M.; the pulse was rapid, the temperature was 100° F., the expression was anxious, and every movement gave pain. She complained bitterly of pain in the left shoulder tip (a symptom that I have found not uncommon in these cases), the abdomen was distended, and the liver dulness was lost. I diagnosed a perforated gastric ulcer. She was removed to the infirmary and I operated at 8.45 P.M., four and a half hours after the perforation. An ulcer was found on the anterior wall of the stomach. There was little or no extravasation of the stomach contents into the peritoneal cavity. I excised the ulcer and the resulting wound in the stomach was secured by two layers of silk stitches. The peritoneum was freely douched with hot saline solution, and no drain was used. Recovery proved uneventful. She left the infirmary in a month. Progress for six months was satisfactory; she had no pain after eating and remained in the best of health. I saw her again at the beginning of this year, because she was complaining of pain under the tip of the left ninth rib, which she described as of a dragging character. It was not aggravated by food. I suspected an adhesion resulting from the operation and advised rest in bed, great care with diet, and, if no relief resulted, to have the abdomen opened to investigate the cause. The patient was not seen again until May 29th, 1904. She had been off and on well since my last visit in February, sometimes free from pain and at others suffering severely, but it now had relation to food. She stayed in bed on May 25th and 26th for this same pain, but on the 27th and 28th she had been better and freer from pain than at any time since the operation. During the afternoon of the 29th she played croquet and afterwards ate a full tea of ham and eggs, and subsequently went for a walk. At 9.15 P.M. or thereabouts she had a drink of milk and soon after complained of severe abdominal pain whilst walking in the street. This was so bad that she had to get a cab to take her home. I first saw her at 11 P.M. and found the abdomen not very distended, but acutely tender to palpation, more especially over the left hypogastric region and in the epigastrium. The liver dulness was slightly diminished, and there was much rigidity of the abdominal muscles. She had vomited and was constantly making slight attempts at regurgitation which brought on severe pain. She could not micturate although there was a constant desire so to do. The pulse was 132, respiration was almost entirely thoracic, the tongue was furred, the breath was offensive, and the temperature was 100·4°. I suspected perforation, although the symptoms were so vague, and strongly urged an exploratory operation. It was now that she begged for morphine and wished me to leave her till the morning, but I absolutely declined. Hence some delay took place and it was not until 1.45 A.M. on the 30th that I was able to operate—four hours after the perforation.

On opening the abdominal cavity many firm adhesions were encountered binding the stomach to the abdominal walls and to the liver; great difficulty was experienced in separating the stomach and when this was done the position of the old ulcer was easily made out, quite obliterated, but in the stomach wall in this position I could feel the silk that had been used in the previous operation. The stomach itself was very much congested. No free gas escaped from the abdominal cavity and there was not much evidence of soiling beyond stray flakes of lymph, so that I doubted at first whether a perforation had occurred, but on gently drawing the stomach into the wound a fresh ulcer fully four and a half inches from the site of the previous perforation came into view with a minute perforation in its centre. The ulcer was close to the lesser curvature and from its proximity to the œsophagus difficult of access. It was of about the size of half a crown, very cartilaginous, and the margins of the perforation were hæmorrhagic in appearance. I found it quite impossible to excise, so closure was effected after some difficulty by two layers of fine silk sutures and a piece of omentum was anchored over the site to give additional security. I determined, in view of her good condition at this stage of the operation, the absence of any severe peritonitis, and to prevent the possibility of recurrence, to perform an immediate posterior gastro-enterostomy. This I did as quickly as possible. Subsequently I douched out the peritoneal cavity with large quantities of hot saline solution, a great deal of which being left in, the abdomen was closed in the usual way. No drain was used. She stood the operation very well and her subsequent progress proved uneventful. There was no regurgitant vomiting; in fact, she has never vomited since the operation. She left the hospital in a month. Her present condition is one of gradually improving health.

CASE 2.—The patient was a female, aged 21 years, having a previous history of gastric trouble. Perforation occurred three hours after a hearty meal. The operation was performed two and three-quarter hours afterwards. I discovered a small perforation on the anterior surface which was easily sutured. Lavage was used but no drain. She made an uninterrupted recovery except for some effusion into the left pleura which subsided without tapping.

CASE 3.—The patient was a female, aged 24 years. There was a vague history of previous gastric disorders. The symptoms commenced three days before she came under my care. She had had violent abdominal pains and vomiting, but as she continued to eat heartily till within 24 hours of admission this was hardly to be wondered at. When I saw her the temperature was 101·2° F., the pulse was 140, and she presented all the signs of acute appendicitis. A large incision was made over the cæcum but I soon saw that I had to deal with a subacute perforation of the stomach. A further incision was made over the epigastrium and my examining finger entered an irregular cavity which was bounded below by the pylorus, externally and above by the lesser lobe of the liver. From this stomach contents were escaping. No attempt at closure was made or was possible. Gauze was packed into the cavity and a big drain was put in the lower opening. Strange to say, except that it was prolonged her recovery was uninterrupted. On the fourth day I extracted a piece of bacon from the upper wound, proving at once the correctness of my diagnosis and the tolerance of the much-abused peritoneum.

CASE 4.—The patient was a female, aged 17 years. There was a long previous history of stomach pain, &c. The first symptoms of pain occurred two days before acute illness. Operation was performed approximately 14 hours after perforation. A perforation on the anterior wall of the stomach was easily found and sutured. There was no lavage, only systematic mopping. A small gauze drain was inserted. Recovery ensued without a bad symptom. Her temperature was 101·2° F. before the operation and the pulse was 122. In three days the temperature was normal and the pulse was 88.

CASE 5.—The patient was a female, aged 23 years. We have very little history of this case. She was admitted to the infirmary 20 hours after perforation in a moribund condition. Operation was performed 23 hours after perforation. On opening the abdomen the peritoneal cavity was literally awash with dark brown fluid. The perforation was close to the pylorus and very difficult to suture. Every attempt was made to cleanse the peritoneum by lavage and a suprapubic drain was used. She died seven hours after the operation.

CASE 6.—The patient was a woman, aged 38 years. This is one of the most interesting and instructive cases that I have seen and is the record of a success and a failure. She was a weakly woman, the mother of ten children, and with a history of gastric ulceration extending over many years. On the morning of Dec. 14th, 1902, in the act of micturition she was suddenly seized with acute pain in the left groin and over the bladder, so severe that she nearly fainted and had to have brandy. I saw her at 3 P.M.; she then presented the following curious train of symptoms. There was a left femoral hernia which was quite recent but which I was able to reduce without difficulty. The abdomen was not distended nor hard; it was exquisitely tender over the epigastric region but she persisted that the chief seat of her trouble was in the bladder. The liver dulness was unaltered and there was no free fluid in the flanks. Her tongue was only moderately furred, there was no vomiting, and the temperature was 100·4° F., but her pulse was thin and rapid at 128. In spite of these vague symptoms I decided to operate and did so eight hours after perforation. On opening the abdomen I found on the anterior surface in the outer third a large indurated gastric ulcer of about the size of a five-shilling piece with a tiny perforation right in the centre of it. I had to excise the ulcer and then brought the big gaping wound together in the usual way, the final *fold in the vertical axis being quite four inches long.* Lavage was used and a suprapubic drain. All went well for five days when she began to get true regurgitant vomiting. We tried all possible means to stop it by syphonage, &c., but ineffectually. So on the evening of the seventh day, *recognising that she must have pyloric obstruction,* I re-opened the abdomen to find that the site of my previous operation was almost obliterated, so complete was the healing. But what I did find was a very marked hour-glass state of the stomach. The communication between the two compartments only admitted my *little finger.* This contrac- [illegible] very long-standing ulceration. I [illegible] a posterior gastro-enterostomy. [illegible] shock in eight hours. My great regret is that I did not discover the whole extent of the stomach mischief at the first operation when, if I had done the two things at the same time, I believe she might have had a better chance.

CASE 7.—The patient was a female, aged 24 years. With regard to her previous history, for some months she had suffered from pain after food and vomiting and her general health had been suffering. She had partaken of a hearty dinner on May 29th, 1903, and during the afternoon had walked a distance of some three miles, when she was suddenly seized with abdominal pain. In spite of its severity she managed to walk home and I was not summoned to see her until 8.15 P.M. On my arrival I found her in intense agony with distended abdomen, constant vomiting, rapid pulse, and slightly elevated temperature. I had no difficulty in arriving at the conclusion that she was suffering *from perforated gastric ulcer and advised her removal to the* Infirmary. [illegible] six and a [illegible] abdomen [illegible] peritonitis due to the escape of gastric contents from a large perforation on the anterior wall of the stomach. The ulcer was excised and the stomach sutured with two layers of silk and over the seat of the wound a portion of omentum was anchored. Very careful and systematic douching of the peritoneal cavity was used, followed by mopping in all available pouches. From the extensive soiling of the peritoneum that had occurred I deemed it wise to employ a suprapubic drain and I also passed a large gauze drain down to the site of the wound in the stomach. For 14 days her progress was uneventful. There was considerable oozing from the pubic drain and also along the track formed by the gauze in the upper abdominal wound, but this gradually ceased and by June 12th both abdominal wounds were soundly healed. On the morning of the 12th she complained of not feeling so well, with a pain in the left axillary region. Examination revealed friction and some dulness over the left base posteriorly. Early in the morning of the next day she had a rigor and the temperature rose to 103·4° F. Aspiration of the pleura revealed nothing although I quite believed an empyema was forming. The rigors were repeated on several days and the temperature remained very irregular but the pulse was not markedly accelerated nor were her constitutional symptoms bad. Events progressed much in the same condition until the 30th when she had another slight rigor and again the aspirator was used, and by plunging the needle deeply in between the ninth and tenth ribs I came upon pus. That afternoon I resected a portion of the ninth rib and on opening the pleura I was disappointed not to find pus. It seemed I had to deal with a subphrenic abscess, so I merely contented myself at this time with stitching the pleura together with a view to opening the deep-seated abscess on a subsequent day. On July 3rd I attempted to find the pus by incising the diaphragm but again my search was fruitless. Therefore I proceeded to make a long curvilinear incision below the ribs and fully exposed the posterior surface of the spleen. *This was firmly adherent in all directions and* I presume the friction heard was caused by peritonitis localised in this position. With my finger I separated the spleen as far as possible but came upon no abscess. Despairing of finding the abscess by these double posterior incisions I re-opened the abdominal wound in the middle line. Apparently everything was perfectly normal; the stomach was quite healed; there was no general peritonitis and I am sorry to say I could in no wise localise the small abscess wherever it was. From this time forward she steadily went downhill. She was seen by Dr. G. Newton Pitt and by Dr. Julius Dreschfeld on more than one occasion. Many attempts were made with aspirating needles to find the pus but all without avail. The physical signs over the base of the left lung were most deceptive. Consolidation with increased voice sounds and amphoric breathing led one to think that a pulmonary abscess was in process of formation, but no evidence of this could possibly be found, the general opinion *being that an abscess had formed in the lesser sac* but was impossible of access. Palpation of the abdomen gave no pain and it was free from any dull area. From the beginning of August, however, her general symptoms seemed to improve and the temperature began to fall, so that from the 9th to the 12th it was rarely above 100°, but on the 13th it went up to 105°. Her condition became most alarming. Feeling matters were in a desperate state I once again used the aspirating needle, pushing it deeply in between the ninth and tenth ribs. At last I came upon the pus which I had so often sought for ineffectually. Leaving the needle in [illegible] the pleura and, [illegible] ed opening in the [illegible] escaping. I put [illegible] ied 24 hours after the operation, two and a half months *after the original* perforation of her stomach.

No post-mortem examination was allowed but the final operation revealed sufficiently the regrettable conditions which led to her death—namely, the slow formation of subphrenic abscess. Possibly the pus which I drew off at the first aspiration emptied the small loculus, so that it became increasingly difficult—nay, impossible—to find it again, as witnessed by the many unsuccessful attempts which were made to reach it both by the aspirating needle and *digital exploration. I have no doubt that the fatal* catastrophe was brought about by the subphrenic abscess bursting into the pleura and causing a rapid septic invasion.

The consideration of this case opens up that debateable question in treatment—whether douching or simple mopping is the better method of cleansing the peritoneum. For myself, I think that every case needs to be treated on its own merits. Where there has been, as in the above case, copious exit of stomach contents aggravated by walking *fully three miles* it seems to me that nothing short of lavage followed by mopping would do good. But there is no doubt that free drainage is all-essential and if a drain in the left lumbar region had been used as well as one over the pubes the result might have been different.

The following is an abstract of the cases that I have operated upon for some of the complications of chronic gastric ulcer.

CASE 1.—A married woman, aged 54 years, was admitted under my care to the Southport Infirmary on Oct. 26th, 1901. There was a history of chronic gastric troubles extending from Christmas, 1897, to the present time. She suffered from severe pain after food with *constant vomiting,* which at times was of a coffee-brown *colour and then* very copious. She had been treated in several institutions for the same complaint and whilst she improved under treatment, with the resumption of her work her symptoms rapidly recurred. She had been under my care during 1900, but had now completely relapsed. After two [illegible] ary she consented to operation [illegible] 11th, 1901, a posterior gastro- [illegible] *A bone bobbin was used. The* stomach presented all the appearance due to chronic ulceration. The anterior wall was much thickened near the pylorus, the veins were enormously distended, and there were several enlarged but discrete glands along the lesser curvature. All went well for 11 days when she had a most severe attack of regurgitant vomiting. Her condition suddenly became most alarming. She vomited six quarts of bilious fluid in 12 hours. All feeding by the stomach was stopped and it was washed out every three or four hours. By these measures the difficulty was overcome and on Dec. 29th stomach feeding was resumed. Her further progress was uneventful and she left the infirmary on Jan. 14th, 1902, better than she had been for years. I have recently heard from her. She is in good health, is able to do her work, is free from pain, and has gained flesh.

CASE 2.—The patient was a man, aged 67 years, who was admitted on August 6th, 1902. His complaint was of constant gastric pain, incessant vomiting, and loss of flesh. Examination revealed a painful area over the pyloric region but no lump could be felt. There was much dilatation of the stomach with subacidity. His urine was free from albumin and sugar but of low specific gravity. His sufferings were so acute that he readily consented to an exploratory laparotomy with a view of performing gastro-enterostomy or otherwise as circumstances might direct. At the operation the pylorus was found to be stenosed considerably and the stomach was very much dilated. A posterior gastro-enterostomy was performed and a bone bobbin was used. As far as the immediate operation was concerned he did very well. Within a fortnight he was eating semi-solid food heartily and without pain. He also began to put on flesh. On the twenty-fourth day after the operation regurgitant vomiting commenced and in spite of all measures adopted this persisted until his death which took place about five weeks after the operation. At the post-mortem examination the kidneys were found to be contracted and granular and I inclined to the view that this condition determined the fatal issue, but at the same time this is open to discussion. The probable explanation from examination of the stomach and bowel is that the loop from the duodeno-jejunal angle was too long. It was the failure in this case that directed my attention so strongly to the importance of making a short loop. At the same time I believe fatal regurgitant vomiting commences much earlier than was the case in this patient. He refused any further operation, otherwise I intended to reopen the abdomen to perform a lateral anastomosis between the two limbs of the loop.

CASE 3.—This case I have referred to above (Case 6). It was a complementary operation to the accident of perforation and the patient died within eight hours of performing the same.

CASE 4.—A woman, aged 28 years, was admitted under my care on Dec. 29th, 1902, and gave a very long history of gastric trouble. She had been in St. Thomas's Hospital under the care of Dr. W. M. Ord so far back as 1891. During the early part of 1901 she was admitted to the Southport Infirmary for hæmatemesis and was discharged relieved after a stay of 15 weeks. Hæmatemesis recurred on Dec. 25th, 1902, and for this she again sought admission. From the constant pain and vomiting she was so reduced that I deemed it best to keep her under observation for six weeks, and under treatment she slowly improved. Operation was performed on Feb. 11th, 1903 There were well-marked hour-glass condition of the stomach and also some stenosis of the pylorus. Posterior gastro-enterostomy was performed with simple suturing and no bone bobbin was used. She made a speedy and good recovery with subsequent absence of pain after eating and a great improvement in general health.

CASE 5.—A man, aged 57 years, was admitted under my care on Oct. 24th, 1903. For 12 years he had been suffering from pain after food. Nine years previously he had severe hæmatemesis. For the past seven years he had made it a practice to wash out his stomach almost every day. A diagnosis of pyloric obstruction was made. On Nov. 7th I operated and found the pylorus so contracted that it would not even admit a small probe. A posterior gastro-enterostomy was performed. There was no regurgitant vomiting and his recovery was uneventful except for the fact that he suffered from troublesome diarrhœa. This I think was to be attributed to the fact that the intestines were unprepared for the sudden demands made upon them when he commenced to take ordinary food with freedom and comfort. He has gained nearly a stone in weight since the operation.

CASE 6.—The patient was a female, aged 28 years. There was a very long history of stomach trouble, vomiting, and hæmatemesis. She had been treated in several infirmaries without more than temporary relief. Operation was performed on Jan. 20th. Numerous adhesions were found binding down the pylorus. There was a large ulcer involving the anterior wall of the stomach. This was adhering to the anterior abdominal walls, leading one to believe that on some previous occasion a perforation had taken place. A posterior gastro-enterostomy was performed and her recovery was rapid. There was no regurgitant vomiting. Before the operation she weighed under six stones and by April 16th, 1904, her weight had risen to 7 stones 6 pounds.

CASE 7.—A woman, aged 42 years, was admitted under my care on Feb. 25th, 1904. She was a fragile little woman suffering from rheumatoid arthritis. She had suffered also from considerable gastric pain and vomiting for many months and in spite of treatment obtained no relief. The operation was performed on March 16th. There was a well-marked hour-glass contraction of the stomach with a large chronic ulcer on the anterior wall and numerous adhesions to the liver and abdominal walls. A posterior gastro-enterostomy was performed and her recovery was uneventful. Her general health improved considerably and she left the infirmary on May 14th for a convalescent home.

CASE 8.—A woman, aged 49 years, was admitted under my care on April 4th, 1904. Her history of pain, vomiting, and hæmatemesis extended over a period of 20 years. With regard to her present condition, she was a pallid woman emaciated to a degree, complaining of great abdominal pain which was aggravated after taking food. There was marked rigidity of the abdominal walls and a sense of fulness and resistance was felt over the epigastrium. Operation was performed on May 5th. I found a large cartilaginous ulcer involving almost the whole of the anterior wall of the stomach. Its diameter was fully five inches and on invaginating the stomach wall the finger came upon a depression in the ulcer which seemed fully three-quarters of an inch deep. There were so many adhesions that the performance of a posterior gastro-enterostomy was exceedingly difficult, but union was successfully effected and her recovery was uneventful. There was no regurgitant vomiting. The patient left the infirmary on June 2nd for a convalescent home. I saw her again on June 20th. Her weight, which before the operation was 6 stones 4½ pounds, was now 6 stones 9 pounds. She was taking her food freely and without pain and the marked pallor of her face was greatly improved.

CASE 9.—The patient was a woman, aged 47 years. She had suffered from dyspepsia and gastric trouble since 14 years of age. From the Christmas of 1903 she had been considerably worse; the pain was not only in the epigastrium but also in the left hypochondrium. This was so severe that it had to be relieved by morphine but food often gave temporary relief. Vomiting was not a marked symptom. Dr. Dreschfeld saw her with me and confirmed the diagnosis of chronic gastric ulcer and strongly urged operation which took place on March 17th, 1904. There was well-marked hour-glass stomach which had dense adhesions to the neighbouring organs, particularly one which went downwards and forwards to be attached to the gastro-colic omentum, probably causing the dragging pain she so frequently complained of in that region. Posterior gastro-enterostomy was effected with some difficulty as there were so many adhesions. Her subsequent progress was uneventful. There was no regurgitant vomiting. She has gained over a stone in weight since April 20th.

CASE 10.—The last occasion on which I had the opportunity of performing a gastro-enterostomy is the one noted above (Case 1) who had suffered from double perforation.

I am well aware that a series of ten cases is too limited to draw any final conclusions from but they are a small contribution to the mass of evidence that is accumulating as to the benefits to be derived from the performance of a posterior gastro-enterostomy in judiciously selected cases.

Southport.

A CASE OF ACUTE DIABETES INSIPIDUS WITH FATAL COMA.

BY ALFRED H. CARTER, M.D. LOND., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO QUEEN'S HOSPITAL, BIRMINGHAM; PROFESSOR OF MEDICINE, UNIVERSITY OF BIRMINGHAM.

THE following case is worthy of being put upon record owing to its rarity. The notes are unavoidably brief as I only saw the case once in consultation and no post-mortem examination was obtainable.

On July 11th last I was called to see a little girl, aged eight years, with Mr. A. E. Hancock of Saltley. The child was reported as being of a nervous and excitable temperament, but, apart from the presence of threadworms in the stools (to which the mother attached no importance and adopted no treatment), she was considered to be in good health until June 25th On that day she went to a school treat, to which she was eagerly looking forward and over which she was very excited The day was showery, but the child does not appear to have got wet, nor did she eat anything beyond a moderate amount of bread and butter and plain cake On the next morning she complained of being unwell, but with no definite symptoms On the following day she seemed to be better but from that time forward she became very thirsty, was always drinking water, and passed large quantities of pale urine The amount was not measured but was said *to be at least from six to eight* pints in the 24 hours Sleep was disturbed owing to the *frequent calls to pass urine but otherwise the child com*plained of nothing, her appetite was good, and she had no pain The mother, thinking that the child s thirst was due to the hot weather, did not seek medical advice Then the appetite gradually failed, the child became pale lost *flesh, and the skin became very dry The diuresis continued* as before On July 10th she complained of pain in the stomach and vomited and Mr Hancock was called in He prescribed diluted milk and a mixture containing liquor bismuthi citratis and morphine ($\frac{1}{48}$ grain for a dose) On the following day the child was better The vomiting had stopped but there was still some uneasiness in the epigastrium I saw the child on that evening and found her drowsy but easily roused Her temperature was subnormal She was reported to have "wandered from time to time in her sleep She had only taken about a pint of milk and *water that day and the amount of urine had fallen* to a corresponding extent The respirations were deep, and were 24 per minute There was no cough The pupils were moderately dilated Beyond the dryness of the skin and emaciation no morbid physical signs were observed The urine (from a sample recently passed) was examined, it was of specific gravity 1018 and pale, there was a trace of albumin but *no sugar* Half a pint of hot normal saline fluid was ordered to be injected into the bowel and repeated every four hours On the next morning I heard that the saline injections had been retained and that the child had taken rather more nourishment but was more drowsy and her breathing was more rapid and panting Nothing was found on examination of her chest As the bowels were confined a dose of castor oil was suggested The next thing I heard was that the child had steadily become worse and died in the afternoon of July 13th

Mr Hancock has since sent me the following note ' The child never spoke after you saw her, the comatose condition increased the amount of nourishment taken was much less but was taken and swallowed up to ten hours before death The amount of urine passed from the time you saw her until death was about one third of an ordinary chamber potful The specific gravity was 1010 reaction slightly alkaline of a very pale colour with a slightly greenish tinge no blood no sugar and a very slight trace of albumin The microscope revealed nothing The rectal injections were retained The *pulse became feeble and compressible* About *one* hour before death it was 90 per minute The respirations increased [illegible] 40 per mi[illegible] ably from [illegible] normal Half an hour before death the conjunctivæ were insensible The castor oil was given but had not acted before death The condition was obviously closely allied to if not identical with the so called Kussmaul s coma in diabetes mellitus

Birmingham

A METHOD OF HYSTERECTOMY

BY JOHN O CONOR, M A, M D DUB

SENIOR MEDICAL OFFICER, BRITISH HOSPITAL, BUENOS AYRES.

As a general surgeon I feel some diffidence in intruding on the preserves of my gynæcological colleagues by inviting attention to a method of removing the womb which I have found both simple and efficacious I do not presume to claim any originality for the procedure as its simplicity dictates the conclusion that if the surgeon in the Ark performed abdominal hysterectomy in all probability he adopted some similar plan However, as I do not remember to have seen *the method described I may venture to publish it*, and before doing so I wish to acknowledge my indebtedness for ideas to Freyer s operation of prostatectomy and O Sullivan s cervical forceps

The patient is prepared for [illegible] light dietary and mild purgati[illegible] twice daily with acid mercurial l[illegible] mercurial sitz bath is given each evening The night previous to operation the skin of the abdomen is carefully cleansed and a mercurial moist dressing applied On the morning of operation the charge nurse gives the vagina a final irrigation the bladder having been previously emptied *Chloroform having been administered the patient is placed* for a few moments in the lithotomy position A nurse introduces two Simon s specula I seize the cervix with a strong Muzeux forceps, and with a large curved scissors rapidly divide the vaginal mucous membrane freely all round above the grasp of the forceps The nurse then removes the specula, without having touched the parts with my hands *I cast the scissors aside* and the forceps is left *in position*

The patient is then placed in the supine position, the dressing is removed, and the skin is finally washed with alcoholic mercurial lotion As I usually operate with two assistants I may mention that up to this stage they have not taken any part in the procedure Sterilised mercurial towels are placed around the field and fixed in position by four of Mr Arbuthnot Lane s most useful tissue forceps The abdomen is then opened the womb differentiated, and the peritoneal cavity packed off with large Turkey sponges I now direct a nurse (not one of my two assistants) to pass her hand up between *the patient s legs* under *cover of the sterilised towel grasp* the Muzeux forceps and push firmly upwards The result of this simple manœuvre is practically to render the operation of hysterectomy a superficial business and obviate in a large percentage of cases the necessity for the Trendelenburg position which ought to be avoided as much as possible as I have on several occasions seen considerable shock follow its adoption This can only be accounted for by the huddling upwards of the abdominal contents A successful issue often depends on a dry pelvis and I am unable to follow the reasoning of some continental surgeons who leave shed blood to be absorbed by the peritoneum

The vesical peritoneal reflection is next divided transversely and the bladder is freely separated from the uterus The womb is then pulled well forwards by an assistant while I transversely divide and free the peritoneum on the posterior surface as low down as seems convenient The ovarian and the round ligament segments of the broad ligaments are ligated and divided *then an assistant draws the womb* to one side and the nurse is now told to push up the forceps firmly while I divide the remaining portion of the broad ligaments close to the uterus until I expose the head of the Muzeux forceps As each branch of the uterine artery is divided it is seized with a Lane s artery forceps The [illegible] to [illegible] I [illegible] and proceed to suture the peritoneal flaps Before closing the abdomen I always devote a few minutes to inspection of the work done and take care to leave the pelvic basin clean and dry

As to ligature material my custom is to use silk inside a clean peritoneum and slippery catgut outside I find that very little blood is lost by this method and all clamping and mass ligaturing *in the dangerous uteric zone are avoided* by the application of a forceps to each vessel as it is divided *I feel confident that if any surgeon wishes to try* this plan he will find the uterine vessels very easy to deal with

My reasons for advocating panhysterectomy are as follows 1 In a considerable number of the patients on whom I found it necessary to perform hysterectomy for fibroid disease there co existed some cervical lesion such as laceration, glandular hypertrophy or chronic endo cervicitis, and I could not quite reconcile myself to the idea that the retention of a diseased stump was expedient 2 In the condition described by Mr J Bland Sutton as fibrosis it would be puerile to remove the body and leave the neck 3 In some cases we are compelled to remain in doubt as to the nature of the tumour until after a post-operative microscopic examination; a mistake on the wrong side would be nasty. 4. The development of cancer in the derelict stump is not unknown. 5. In cases of cancer and cervical fibroids panhysterectomy has to be performed. 6. If parametric drainage should be required I do not consider the stump of the cervix an ideal drain—i.e., an aseptic one providing free and spontaneous drainage. 7. I have found by experience that vaginal hernia does not take place if the vaginal wound is sutured and rarely does so even when this detail is omitted.

Buenos Ayres.

MENINGEAL INFECTION BY THE DIPLOCOCCUS PNEUMONIÆ, SIMULATING INFECTIVE CEREBRO-SPINAL MENINGITIS.

BY W. G. BARRAS, M.D. GLASG., L.S.SC. DURH., D.P.H.,
BACTERIOLOGIST, BURGH OF GOVAN.

THE clinical history of the following case presents several features of unique interest analogous to those met with in some cases of epidemic or infective cerebro-spinal meningitis, but differing from the latter in that it was due to an accidental and somewhat unusual infection by the diplococcus pneumoniæ. As will be observed from the clinical data, supplemented by the results of the post-mortem and bacteriological examinations, the case is one which is instructive, in so far as it is reasonable to suppose that cases of a similar nature in which the diagnosis is that of ordinary meningitis might be due to a like infection.

The patient, a boy, aged five years, was at school until April 11th apparently in good health, but on the morning of the 12th he complained of severe headache accompanied by persistent vomiting, and when seen by me on the 14th these symptoms still continued, besides which he was exceedingly restless, throwing his head back, tossing about in bed, grasping his head between his hands as if in severe pain, and clutching at his throat. At this stage the pupils were widely dilated. As the case was regarded as one of meningitis of rather an obscure nature he was removed to the Elder Cottage Hospital, Govan, by which time he had become comatose.

I have here to express my thanks to Dr. Hunter, physician to the hospital, for kindly furnishing me with the following history of the case from his admission until his death on April 16th, as well as for the results of the post-mortem examination of the head. On the afternoon of the 14th the patient was admitted to hospital in an unconscious condition. At first he was restless, tossing about in bed, and muttering constantly. Once or twice he asked for milk and showed doubtful recognition of his mother for a moment. There was marked hypersensitiveness to sound and to touch. The pupils were widely dilated and did not react to light. The plantar reflexes were normal. The heart and lungs were normal. The breath was markedly offensive, the odour being suggestive of what is found in diabetic coma. The lips were rather livid and cracked. The tongue was dry with some brownish fur on the dorsum. The urine, which was passed involuntarily, was loaded with urates but showed no trace of albumin or sugar. The bowels had not been moved for about 30 hours but an enema brought away rather a large motion with some hard masses. Difficulty was experienced in getting him to swallow food or medicine and recourse was had to rectal feeding. The temperature taken in the rectum on admission was 103·8° F., there being considerable oscillation, it once falling to 98·6° within 24 hours of admission, but ranged mostly between 101·2° and 103·6°. Just before death it rose to 106° in the axilla. The pulse varied in rate considerably from 104 to 142 per minute, being always compressible and at times counted with difficulty. Respiration never showed a cerebral character and ranged from 34 to 42 per minute. The pupils within 24 hours of admission became rather small and reacted readily to light and so remained. Tremor was noted in the muscles of the arms and there was marked orthotonos of the neck and upper dorsal region. Unconsciousness gradually deepened and the patient died about 40 hours after admission, the duration of the illness being about five days.

Necropsy.—A post-mortem examination was made of the head. The skull was rather thin. The dura mater was normal. The pia mater throughout was deeply congested and there was very little serous effusion on the surface of the brain. Over almost the whole convexity and base of the brain fibrinous pus was noted. The spinal cord was not specially examined but the part removed with the brain seemed less deeply injected and no pus was found on its surface. There was no trace of tubercle.

With regard to his previous history the boy had hitherto enjoyed good health, with the exception of measles and whooping-cough when about 12 months old. A physical peculiarity remarked upon by his mother was that he had a very short neck. As to the family history, the father is in good health but the mother is of a nervous temperament and is frequently subject to attacks of hysteria. The other members of the family, four in number, are all alive, although one sister at the age of 15 months suffered from convulsions and has been very nervous ever since. Another sister at the age of nine months had an attack of inflammation of the brain.

Bacteriological examination.—Cover-glass specimens prepared from the meningeal exudate showed in every instance large numbers of capsulated and extracellular diplococci. These were readily stained by the ordinary aniline dyes as well as by Gram's method. The diplococci were also well seen in smear preparations from the brain tissue. From these facts the conclusion arrived at was that the illness in question was a meningitis the result of infection by the diplococcus pneumoniæ. In such cases, however, the inflammatory condition is generally secondary to an attack of acute lobar pneumonia, as a result of extension from disease of the nose and ear, or from the effects of an injury to the skull. In this case, however, no such conditions existed and it can therefore only be regarded as a primary pneumococcic infection. The symptoms during life at one time gave rise to the suspicion that it might possibly be due to the diplococcus intracellularis meningitidis of Weichselbaum, but this view of the case was not borne out as a result of the bacteriological investigation.

HÆMORRHAGIC SMALL-POX:

A CLINICAL NOTE OF 36 CASES.

BY CHARLES FRASER, M.A., M.D. EDIN.,
ASSISTANT MEDICAL SUPERINTENDENT, ST. PANCRAS INFIRMARY (SOUTH); LATE RESIDENT MEDICAL OFFICER, DAGENHAM SMALL-POX HOSPITAL.

THE frequency with which cases of hæmorrhagic small-pox properly so-called occur varies in different epidemics. Of 1200 cases of small-pox treated at Dagenham Hospital during the epidemic of 1902 36 belonged to this variety—i.e., 3 per cent. of all cases. It is convenient to recognise three types of this condition—viz: Type 1, characterised by the appearance during the initial stage of the disease of hæmorrhagic changes in the skin and visible mucous membranes, resulting in the production of petechiæ and ecchymoses, the patient almost invariably dying before the characteristic small-pox eruption has had time to declare itself; Type 2, including all cases in which the hæmorrhagic element involves not only the region of the pock but areas free from eruption; and Type 3, those cases in which the area of the pock alone is involved. In all three it is important to remember that, in addition to the production of petechiæ, the hæmorrhages may assume the form of epistaxis, hæmoptysis, hæmaturia, hæmatemesis, or melæna. The "pseudo-hæmorrhagic" case of the text-book is excluded from the present survey, as it displays none of the special features of the hæmorrhagic case proper. We shall consider each type separately.

Type 1.—Five cases belonged to this variety. Authorities appear to be unanimous in the view that the condition occurs almost exclusively in adults who had previously been robust and vigorous. The writer in Allbutt's System is of opinion that men are more frequently affected than women, whereas the writer in Nothnagel's Encyclopædia is responsible for the opinion that women are more often the victims, especially pregnant and puerperal women. The average age of our cases was 37 years, the youngest being

15 and the oldest 72 years. Four were women, but none of these were pregnant nor in the puerperium. All were of average physique and had previously enjoyed good health. The writer in Allbutt's System mentions that the condition is usually found in vaccinated persons. This is probably merely a coincidence; for he goes on to state that he has never found it in a person who had recently been vaccinated and presented a third of a square inch of well-foveated vaccination cicatrix.[1] The five cases under consideration had all been vaccinated, and four of [illegible] as having been "well vaccinated"—i. [illegible] more scars which were distinctly pitte[illegible] in all cases been neglected. All ended fatally, the average duration of illness being only four and a half days. The most severe case was that of a woman who died on the second day of her illness.

Clinical note.—The state of the patient on admission was in all these cases much the same. Extreme prostration with absolute flaccidity of the whole muscular system and blunting of the intellectual functions were prominent features. Delirium of the low muttering, asthenic type was evident in all from the date of admission till death. The unclouded mind, regarded by many authorities as a peculiarity of this type of small-pox, was not observed. In all the patients the special hæmorrhagic symptoms were in full evidence on admission. In one only—a woman aged 72 years—the hæmorrhagic change, so far as external evidence showed, did not involve internal organs. Vomiting in an aggravated form occurred in one case only. The other four patients took nourishment well and were able to retain it. Considering the profound degree of the asthenia which characterised the cases the state of the heart was wonderfully good. The pulse varied from 120 to 140 per minute, was of fair tension, and rarely displayed any marked irregularity. This state of things continued until perhaps an hour or two before death, which appeared to be due to syncope. When circulatory failure did occur it came suddenly and was complete. In none of the cases was there any œdema of the face or other parts. There were no physical signs in the chest to suggest the presence of lung mischief. The respirations, however, were hurried. Osler appears to regard this acceleration of respiration in the absence of physical signs in the chest in conjunction with the comparatively moderate degree of pyrexia as of some diagnostic value.[2] From a composite chart of the five cases one observed that on the evening of the second day in hospital a temperature of 101·2° F. occurred with respirations at 48 per minute, and on the third day a temperature of 99° with respirations at 64.

Type 2.—21 cases belonged to this variety. It is said to occur most frequently in the debilitated, the alcoholic, &c., and men are reported to be affected more often than women (Nothnagel). 14 of our cases were men and several of them were big, robust fellows who had previously enjoyed good health and led regular lives. 14 had been vaccinated in infancy, nine of these having been "well vaccinated." All had failed to be revaccinated, and it is noteworthy that the two youngest patients, aged three and six years respectively, had never been vaccinated. All died, the average duration of illness being 6·9 days.

Clinical note.—On admission the general aspect of patients belonging to this group was one of intense fatigue. When not actually delirious they exhibited the same tiredness of intellect which characterised their bodily functions. Prostration was quite as profound as in the last group. Many complained of headache and backache; some complained of discomfort in the region of the stomach, and this was sometimes accompanied by vomiting. All had evidence on admission of the hæmorrhagic changes. In ten cases these manifestations became extreme. In four there was an entire absence of internal hæmorrhages. Indeed, these did not appear to have any relation to the virulence of the attack, for in the severest case of the group they were conspicuous by their absence. The typical small-pox rash was of the confluent variety, and in the case of the patient who lived longest it reached a condition of filmy vesiculation—confluent both on face and trunk. Delirium was a pretty constant symptom in this type of case. At first active and often dangerous—although the patient was incapable of any very sustained effort—it assumed the adynamic type towards the close. In only two cases was the symptom absent throughout their illness. Alert and full of apprehension, these men seemed to realise fully the extreme gravity of their condition. The heart did not at first give any sign of greatly failing power. The pulse varied from 110 to 130 and was regular—the tension being better and the vessel fuller than in Type 1. A few hours before death it became very weak, however, and death appeared to be due to syncope. The signs of circulatory failure appeared somewhat earlier relatively than in Type 1. In a few, towards the end of the illness, there was some œdema, especially of the face, but never very pronounced. A study of a composite chart of all [illegible] showed an evening temperature of 101° or 102°, [illegible] pirations increasing from 26 on admission to 48 [illegible]ath.

Type 3.—Ten cases were of this variety. The average age was 26·8 years and the condition was equally distributed between the sexes. Two patients, aged respectively six and 14 years, had never been vaccinated, and of the others all with one exception had been vaccinated in infancy. Six had been "well vaccinated"; and it is worthy of mention that the only case of recovery was that of a man, aged 30 years, who exhibited five very distinct vaccination marks. He remained in hospital 41 days. One patient, aged 30 years, gave a history of having been revaccinated six days before the onset of his illness, and he died on the twelfth day of the disease. The operation as performed in infancy had been imperfect, the scars being faint and indistinct and of small area. A patient, aged 28 years, stated that she had been vaccinated for the first time ten years previously. The scars, however, were very faint and the patient died on the eleventh day of her illness. The average duration of the illness in the nine fatal cases was 10·7 days.

Clinical note.—The cases belonging to this group usually presented, on admission, the appearance of the early stage of confluent small-pox, and there was an entire absence of evidence to suggest that graver changes were impending. The initial symptoms had been severe, especially the headache and backache. As a rule the patient was in the full possession of his mental faculties. By the end of the third day of his illness the rash on the forehead had reached a condition of full papulation, the individual papules merging over large areas. A few hours later commencing vesicular changes were visible. In the course of the next 24 hours, as a rule, the hæmorrhagic element had declared itself by a darkening of the vesicles and the development of a petechial ring round individual vesicles or groups of vesicles. According to the severity of the case the changes were limited to the extremities or involved the trunk as well. With their advent the aspect and whole demeanour of the patient approached that of the last type. He became restless and anxious, and if he retained his intellectual faculties he seemed to anticipate a fatal issue. In five cases delirium was absent. When it occurred it appeared late and was of the low type and lasted until the death of the patient. Hæmorrhage from internal organs was less common than in the last two types, being entirely absent in five cases. The general condition of the circulation was good for the first few days. In the later stages the pulse became irregular and weak, increasing in frequency from 110 to 140 per minute. This condition of circulatory weakness lasted longer than in the former two types. Œdema of the face, &c., was prominent in most cases. Death did not appear so clearly to be due to syncope as to a general exhaustion the result of the profound toxæmia.

On glancing at the cases as a whole one or two facts remain to be recorded. In the first place, the unvaccinated person suffering from small-pox appears to be more liable to this type of the disease than the vaccinated. In the present instance 3·3 per cent. of unvaccinated cases suffered from the hæmorrhagic type, as against 3·1 per cent. of the vaccinated. Further, the young tend to escape—only three out of the 36 cases being under ten years. Out of a total of 1200 cases of small-pox there were 198 persons under the age of ten, practically all of them being unvaccinated; 1·5 per cent. of these suffered from the hæmorrhagic variety, as against 3·3 per cent. of all cases over that age. The average age for the whole series is 32·4 years. Men were more frequently affected than women, in the proportion of 20 to 16. An interesting fact which ought not to escape notice was the voraciousness of the patient's appetite and his ability to retain and utilise nourishment. In a few cases gastric derangement with vomiting was prominent and even in these cases one noted an anxiety for the food which they were unable to retain. This seemed to be a characteristic of small-pox patients in general and the increased gravity of this particular type did not appear to diminish the desire for nutriment.

FORMALDEHYDE IN MILK.

BY W. SCOTT TEBB, M.A., M.D. CANTAB.,
PUBLIC ANALYST TO THE METROPOLITAN BOROUGH OF SOUTHWARK.

IN view of the recent outbreak of "epidemic skin disease"[1] the accurate estimation of formalin[2] in milk becomes a matter of considerable importance and the object of the present paper is to recommend to notice the following process which will be found to give trustworthy results. The method depends on the pink colour which develops when fuchsine decolourised with sulphurous acid (Schiff's reagent) is added to the clear filtrate obtained after the precipitation of casein and fat from diluted milk. It has long been known[3] that if milk is diluted and acidified the whole of the casein and fat may be precipitated, leaving a clear liquid on filtration. I first made experiments to see if milk containing formalin would retain the preservative on being subjected to this treatment and also if the depth of colour given by the Schiff's reagent was in proportion to the amount of preservative present. These preliminary tests were entirely satisfactory and I have since worked out the process in detail as follows.

To precipitate the casein and fat from milk.—To estimate formaldehyde by this process it is essential to obtain a perfectly clear filtrate from the milk and after numerous experiments the following is the method which I have found to answer best. 50 cubic centimetres of the sample are measured out into a tall cylindrical glass of 250 cubic centimetres capacity, the glass is filled up to the 250 cubic centimetre mark with water, the milk and water are well mixed together, and then is added 0·4 cubic centimetre of a 25 per cent. solution of sulphuric acid. The mixture is well agitated with a glass rod for a minute or so. The casein and fat will then separate as a coarse precipitate, leaving a more or less clear liquid at the top. The precipitate is allowed to settle for about five minutes and then the liquid is filtered. I use a large funnel of four and a half inches diameter with Chardin filtering paper which must first be well wetted. In the majority of samples the filtrate will come through quite clear but occasionally it will be opalescent or even milky; when this happens the remainder of the 250 cubic centimetres should be poured on to the filter and it will be found that after about 100 cubic centimetres have gone through the filtrate will become quite clear; this is owing to the precipitate itself lining the inside of the filter and increasing the filtering power of the paper. By attention to these details I have never had any difficulty with fresh milk and have often been successful with milk a day old, but, as I shall presently point out, for reasons connected with the rapid disappearance of the formaldehyde, whenever possible the analysis should be conducted on the day the sample is purchased.

Preparation of the Schiff's reagent.—One gramme of ordinary crystalline fuchsine (*not* the acid fuchsine) is weighed out and placed in a 50 cubic centimetre flask, which is filled up to the mark on the neck with a cold *saturated* solution of sulphurous acid in water. The sulphurous acid solution may be conveniently prepared by means of a syphon of the compressed gas. After standing for several hours the fuchsine loses its colour and goes into solution, the liquid assuming a light yellow tint. Then the 50 cubic centimetres are diluted to one litre with distilled water and proceed as follows. Two Nessler glasses are taken, to one of them is added 0·5 cubic centimetre of a 1 in 1000 dilution of formalin, and both glasses are filled up to the 50 cubic centimetre mark with water; then five cubic centimetres of the Schiff's reagent are added to each glass, which is stirred and allowed to stand for ten minutes. It will be found that both Nessler glasses show a marked pink colour—that is to say, that at this stage the simple dilution of the reagent with water will give a similar reaction to the formaldehyde. To make the Schiff's reagent sensitive sulphurous acid gas is bubbled in from the syphon for about ten seconds at a time until a point is reached when it will react in the Nessler glass containing formalin, but not with the plain water after standing for ten minutes. If the reagent is too strongly impregnated with sulphurous acid it will cease to react to the formalin and hence the care required in conducting these operations. I find that 250 cubic centimetres of the Schiff's reagent prepared as above (0·1 per cent. fuchsine) will be made sensitive by bubbling in the gas at a medium rate for about 30 or 40 seconds.

Application of test.—50 cubic centimetres of the clear filtrate from the sample of milk are poured into a Nessler glass, five cubic centimetres of the Schiff's reagent are added, and the mixture is allowed to stand for ten minutes. In estimating small traces of formaldehyde, which may readily be done if the Schiff's reagent is sufficiently sensitive, it is advisable to allow the liquid to stand for a longer period—that is to say, for half an hour or even an hour. To estimate the exact percentage of formaldehyde a number of standards must be prepared of known amounts of formalin added to milk. Each standard is treated by precipitation, filtration, &c., in precisely the same manner as the sample. The Schiff's reagent is then added and the colour of the sample in the Nessler glass is matched with the nearest standard. In ordinary milk adulteration I should expect to find from 0·002 to 0·001 per cent. of formaldehyde and should make up eight standards containing 0·002 per cent., 0·001 per cent., with six intermediate percentages. If the Schiff's reagent is already prepared the whole analysis, including the precipitation, filtration, &c., of the eight standards can easily be completed within the hour.

The following experiments were carried out to show for how long after the addition of the formalin it is possible to detect it in the milk:—

TABLE I.

Percentage of formaldehyde added to milk.	Percentage of formaldehyde detected—					
	After 5 hours.	After 21 hours.	After 29 hours.	After 45 hours.	After 53 hours.	After 72 hours.
0·0055	0·0047	0 0047	0·0045	0·0032	0·0024	0 0001
0·004	0 004	0·0034	0·00285	0·0017	0·00135	0·00005
0·0025	0·0017	0 0017	0·0016	0·00037	0·00017	None found.
0·001	0·00083	0·00025	None found.	None found.	None found.	None found.

The temperature taken at the time of the experiments varied from 21° to 23° C. It will be observed from the table that the length of time formalin may be detected in the milk depends on the amount added. Thus with 0·0055 per cent. or 0·004 per cent. a considerable proportion was present at the end of 53 hours. With 0·0025 per cent. a large quantity remained for 29 hours, while in the case of 0·001 per cent. almost all the preservative had disappeared by the following day. Table II. is a record of a further series of similar observations.

TABLE II.

Percentage of formaldehyde added to milk.	Percentage of formaldehyde detected—		
	After 5 hours.	After 24 hours.	After 48 hours.
0·005	0·005	0·00375	0·00025
0·0025	0 00156	0·0015	0·00020
0·001	0·0008	0 00020	None found.

These results agree generally with those given in Table I.; the formaldehyde, however, disappeared more rapidly. This was in all probability due to the warm weather experienced at the time that the experiments were conducted (from 24° to 27° C.).

The next table gives estimations of the lactic acid and must be considered in conjunction with Table II. The observations recorded in the two tables were carried out under precisely similar conditions. Thus they were made at the same time, on the same morning's milk, and the percentages of formaldehyde added in each case were identical. The object of these experiments was to discover whether the inability to detect formalin after certain intervals of time was accompanied by any loss of preservative power as shown by excess of lactic acid. The acidity was determined by titration with one-tenth normal caustic potash using phenol phthallein as an indicator and calculated as lactic acid. The figures for unpreserved milk are given as a control. At the time of purchase the milk exhibited *an acidity of 0·099* per cent. calculated as *lactic* acid.

---

[1] See Dr. Monckton Copeman's Report to the Local Government Board on an Outbreak of Epidemic Skin Disease at the Central London Sick Asylum, Hendon, No. 194, April 19th, 1904.

[2] Solution of 40 per cent. formaldehyde in water.

[3] See "A Course of Practical Elementary Physiology," p. 121. Foster and Langley, 1880.

TABLE III.

—	Percentage of acidity calculated as lactic acid.		
	After 5 hours.	After 24 hours.	After 48 hours.
Unpreserved milk	0·198	0·658	0·720
Milk 0·005 per cent. formaldehyde	0·144	0·184	0·697
Milk 0·0025 per cent. formaldehyde	0·144	0·261	0·810
Milk 0·001 per cent. formaldehyde	0·135	0·693	0·733

On comparing Tables II. and III. it will be found that when formaldehyde is present it checks the development of the lactic acid. Thus after 24 hours 0·005 per cent. formaldehyde becomes 0·00375 per cent. and is associated with 0·184 per cent. lactic acid, but on the further reduction of the formaldehyde at the end of 48 hours to 0·00025 per cent. the lactic acid is increased to 0·697 per cent. This shows that after a lapse of time formalin in milk not only ceases to respond to chemical tests but also loses its preservative powers, thus indicating that in all probability it undergoes some fundamental change.

Southwark, S.E.

TWO CASES OF POISONING BY MUSSELS—ONE FATAL.

BY R. ROLFE, M.B., B.C. CANTAB.,

MEDICAL OFFICER TO THE NEW DOCK HOSPITAL, AVONMOUTH.

ON the afternoon of July 13th two sailors, one aged 57 years and the other aged 70 years, gathered some mussels from a dock gate. It was known that the water was polluted by sewage but in spite of this the inhabitants of the place often ate shell fish gathered from this situation. The mussels were carefully washed and cooked thoroughly in several changes of water. They were then eaten, flavoured with salt and vinegar. About four hours after the meal both men were seized with giddiness. They described the feeling as like that of gradually wading into water out of their depth. Their legs became unsteady and they felt as if "they could fly." They were soon unable to stand and were taken below and medical aid was summoned. The first-named patient vomited several times. When first seen the signs and symptoms were much alike in both cases. The patients complained of giddiness and were unable to sit up in bed. They had slight abdominal pain. There was mental excitement and the condition resembled closely the early stages of alcoholism. The pulse was full and bounding but not increased in rapidity, being 76 in one case and 80 in the other. The heart sounds were clear and loud. The temperature was normal. There was numbness of the extremities, especially the hands, and sensation was much diminished. The elbow and knee reflexes were present and not exaggerated. The pupils were dilated but reacted to light. In both cases the abdomen was distended and tympanitic but there was only very slight tenderness on firm palpation in the epigastric region. As it was now five hours after the eating of the mussels the stomachs were not washed out but a moderate dose, one and a half ounces of oleum ricini was given in spirit. Both men, however, began to experience dryness in the throat and a feeling of constriction in the neck. Quite suddenly the first named patient had an attack of syncope and died. The symptoms in the case of the other patient grew gradually worse. His abdomen became more and more distended and he was slightly delirious and was with difficulty restrained in bed. At each attempt to rise a syncopal attack was brought on and he *complained much of difficulty in* breathing. This difficulty was

cold compresses on the neck

applied to the abdomen to relieve

much result. Hot strong coffee was given by the mouth but the patient had the greatest difficulty in swallowing it and very small quantities had to be given at a time. The effect was very marked, the patient feeling much better after each drink, but this result was transient and the coffee had to be repeated frequently—about every half hour. Aromatic spirit of ammonia was given in a half-drachm dose in hopes of relieving the abdominal distension, but though the spirit was diluted to one ounce a bad result was produced, the patient nearly choking and a syncopal attack following. As the oleum ricini showed no signs of acting after six hours a large soap and water enema was administered with good result. The patient felt much better after this and was able to be removed to the Avonmouth Cottage Hospital. On admission a draught containing saline aperients and cascara was given but no result was produced in three hours, so further enemata were resorted to. Under this treatment the patient made rapid improvement. The tongue, which had become very furred and dry, cleared and the restlessness passed off and the patient fell asleep. On awaking he complained of headache and giddiness, but these symptoms passed off in two days. On admission his urine contained half albumin; on the next day this amount had diminished to one third and on the following morning to less than one sixth. When seen four days afterwards the patient felt quite well. The urine still contained a trace of albumin but this may be accounted for by old kidney disease. The patient admitted that he had suffered from Bright's disease.

The post-mortem examination of the first named patient revealed nothing special. The usual signs of heart failure were present and the heart was even more flabby than is generally the case. The mucous membrane of the stomach, the duodenum, and upper part of the jejunum was pale. The brain was also anæmic. There was no macroscopic change in the kidneys, which appeared quite healthy, nor was the spleen enlarged. The urine drawn from the bladder con-

cases were (1) the difficulty

the system, as neither flatus

under the influence of purgatives, the gut appearing to be paralysed; (2) the tendency to syncope if the patients attempted to sit up; (3) the afebrile course—in neither case did the temperature rise above normal; (4) the comparative infrequency of the pulse, which never rose above 80 even when syncope threatened; and (5) the marked beneficial effect of coffee on the pulse and on the general condition of the patient. It is curious to note that the first named patient, who was 13 years younger than the second, who vomited freely comparatively soon after eating the mussels, and who had presumably healthy kidneys, succumbed to the toxins which the other resisted. Both men had eaten about the same number of fish.

Avonmouth, Gloucestershire.

A NEW PATHOGENIC BACTERIUM CAUSING BASAL MENINGITIS IN INFANTS.

BY W. D'ESTE EMERY, M.D., B.SC. LOND.,

CLINICAL PATHOLOGIST TO KING'S COLLEGE HOSPITAL; PATHOLOGIST TO THE CHILDREN'S HOSPITAL, PADDINGTON GREEN.

CASE 1.—A male, aged one year and ten months, was admitted to the Paddington Green Children's Hospital, under the care of Dr. Guthrie, with a history of six days' illness, the symptoms being drowsiness and vomiting. There was no history of otorrhœa. When admitted he was apathetic and drowsy but not comatose and apparently not in pain. There was no squint and the pupils were contracted but reacted to light. There were no convulsions and no rigidities; the reflexes were normal. Kernig's sign was not given. There was a well-marked tache. Three days after admission there was definite retraction of the head and the patient had several convulsive fits with general rigidity of the body and limbs and conjugate deviation of the head and eyes to the left. On the next day there was internal squint of the left eye and the pupils were dilated and did not react to light. Six days after admission the respiration was affected, becoming sighing and irregular. The eyes were examined and the retinal vessels were found to be congested; the discs were pale, with indistinct edges. The convulsions ceased. Eight days after admission lumbar puncture was performed. The fluid was quite clear and contained but a trace of albumin. The microscopical appearance of films from the deposit of the lumbar puncture fluid and the result of cultures will be described below. The temperature on admission was about 100°F. and rose gradually and fairly uniformly until death occurred, reaching 104° as its maximum. The child died nine days after admission, or 15 days after the onset of the disease, and the day before death seemed to suffer from pain in the left ear.

Necropsy.—At the post-mortem examination extensive basilar meningitis was found. There were large and thick collections of greenish lymph of gelatinous consistency in the region of the anterior perforated space, the tips of the temporo-sphenoidal lobes, and under the central lobe of the cerebellum, but thinner sheets of the same material united these main collections and extended along the vessels, especially in the Sylvian fissure. The condition was practically symmetrical. The surface of the brain was hyperæmic and the convolutions were flattened. The ventricles were moderately distended with fluid which was colourless and slightly turbid. The right middle ear was normal, containing only the mucoid material so commonly seen in young children. The left contained thick pus. The membrane was intact on both sides. The sinuses were normal. Cultures and films were made from the cerebral pus and films were made from the pus in the left middle ear. There were no other morbid appearances in the body except that the retroperitoneal and mesenteric glands were enlarged but apparently not tuberculous. The films prepared from the cerebro-spinal fluid obtained by lumbar puncture showed but few cells, those present being mostly degenerated endothelial plaques. They showed vast numbers of organisms which were so variable in shape and size as to indicate the presence of a large number of species. The prevailing form was a diplococcus which varied greatly in size, the smallest forms being no larger than meningococci whilst the largest were fully three times that size. The individual cocci were quite round, or more frequently short cylinders with rounded angles. There were also single coccoid forms, often of large size (3μ or 4μ in diameter). Lastly, there were numerous bacillary forms which resembled the individual cylindrical cocci mentioned above but in which the length was three or four times greater than the breadth. They showed very marked polar staining. There was no sign of spore formation. Slight indications of the presence of a narrow capsule occurred but this might have been an artefact. The organisms did not stain by Gram. They were almost entirely extracellular. The culture was prepared by allowing the fluid to flow directly from the needle on to ordinary agar and after 24 hours' incubation presented numerous isolated colonies. Three of these were common air organisms (two of sarcina alba and one of micrococcus roseus) whilst the remainder were similar to one another and of a greyish-white colour. Films prepared from these latter colonies showed the presence of an organism exactly resembling those seen in the films except that coccoid and bacillary forms predominated, the diplococcoid form being comparatively infrequent. Some giant diplococci of large size and great affinity for stains were present. The appearances of the colonies indicated that they were pure but they have been repeatedly plated out without losing any of their characteristics. The films made from the pus from the ear and from the meningeal exudate showed organisms exactly like those seen in the lumbar puncture fluid, but unfortunately no cultures were made.

CASE 2.—A male, aged nine months, was admitted to the Paddington Green Children's Hospital under the care of Dr. Sutherland, having been ill for one month. The illness began by convulsions and vomiting. The latter continued but the former passed off and was replaced by twitchings of the hand and head. Four days before admission his neck became stiff. On admission the child was conscious but apathetic; he lay on his back with his legs in a position of flexion. The pupils were moderately contracted and reacted well and there was no squint. There was a slight nasal discharge. The tympanic membranes were examined and appeared to be healthy. There was a slight tache and Kernig's sign was present on both sides. There was occasional vomiting. After a day or two in hospital he became extremely restless, with constant twitching of the extremities, cerebral breathing became marked, and the abdomen became retracted, whilst the rigidity of the neck increased. Eight days after admission lumbar puncture was performed. The fluid had a yellowish tinge and contained a large quantity of albumin. From this point the child steadily went downhill and died 19 days after admission, or about seven weeks from the onset of the disease. The temperature on admission was about 98° F., with occasional brief excursions to 100° or thereabouts. It rose gradually until it averaged about 101° and remained so until 36 hours before death, when it suddenly rose to 107°.

Necropsy.—The post-mortem appearances in this case were quite similar to those in the foregoing but more marked. Large masses of creamy, greenish-yellow pus occurred beneath the pia mater at the anterior perforated space and the tips of the temporo-sphenoidal lobes whilst there was but little on the lower surface of the crura and cerebellum. The pus tracked alongside the vessels on to the hemispheres but not to so great an extent as in the previous case. Here, however, there was a great excess of turbid fluid in the pia-arachnoid space at the base of the brain, a condition which did not occur in the previous case. The convolutions were flattened and the meninges over them were hyperæmic. The ventricles were greatly distended with turbid fluid and contained coagulated masses of creamy, yellowish-green pus. The lining membrane of the whole ventricular system was injected and apparently œdematous, yet moderately tough; it could be readily peeled away from the subjacent tissues and had the general appearance of granulation tissue. The iter was greatly dilated. The spinal cord was also affected, a layer of greenish pus extending down the dorsal surface as far as the conus medullaris. The middle ears were full of greenish pus similar to that seen in the brain and the membranes were intact. There was no thrombosis of sinuses. The abdominal lymph glands were enlarged but not caseous. Nothing else abnormal was noticed. Cultures and films were made from the pus from the brain and ears. The films prepared from the lumbar puncture fluid in this case were richer in cells than in the foregoing, highly degenerated polynuclears being present as well as endothelial cells. Here also there were vast numbers of organisms, the predominating form being a bacillus which was about as wide as those present in the previous case, or a little narrower, and of very variable length; the shorter forms were but slightly longer than they were wide, and the longest forms were leptothricial filaments reaching a third of the way across the field of a $\frac{1}{12}$ inch lens. In the more abundant forms the length was about four or five times the breadth. Polar staining was fairly well marked, there was no spore formation, and they did not stain by Gram. They were mostly extracellular, though clustered about the cells, but in a few cases they seemed to be engulfed and to lie in vacuoles in the protoplasm. There was the same doubtful appearance of capsulation. In this case coccoid and diplococcoid forms occurred, but were uncommon. In the films prepared from the pus from the ears and meninges of this case similar bacteria were seen but were much less numerous; here also the bacillary forms predominated, though large diplococcoid forms occurred. Capsulation was better marked.

So different were the appearances of the organisms in the above cases that their identity was hardly suspected until cultures made from the meningeal and tympanic pus were examined. These showed abundant growth in 24 hours and both were pure, presenting on microscopic examination appearances identical with those seen in the culture from the lumbar puncture fluid in the first case. The cultural characters have not been worked out in full but the following features will probably suffice for the recognition of the organism. The growth on agar at 37° C. was extremely rapid, isolated colonies acquiring a diameter of three or four millimetres or even more in 24 hours. They were white or greyish-white in colour, opaque, and were circular in shape and often had slightly raised edges. They rapidly extended and the whole surface of the medium was soon covered with a uniform whitish layer. Streak cultures on agar showed a similar flat growth which spread quickly. The organism grew well on gelatin at the ordinary temperatures. Streak cultures showed a featureless ribbon-like growth similar to that seen on agar but without the same tendency to spread. Stab cultures were more characteristic. The growth was white or slightly grey and opaque. It extended to the bottom of the stab but was slightly more abundant at the top, whilst

on the free surface there was a rounded button of growth very similar to that seen in cultures of bacillus pneumoniæ The gelatin was not liquefied Growth in broth was not very abundant At first the medium was uniformly turbid, whilst after a time there was a slight deposit No scum was formed The microscopic appearances of the organisms from the cultures were on the whole similar to those seen in the lumbar puncture films in the first case, but there were minor
forms predominated and in
Diplococci also occurred
-tion of bacilli, some of them
quite long and in some cases clubbed or spindle shaped They stained uniformly or showed polar staining, and there were no spores The organism was non motile and did not stain by Gram

CASE 3 —This case does not call for prolonged notice The patient was a girl, aged two years and eight months, who was admitted to the Paddington Green Children's Hospital under the care of Dr Guthrie She was ill for 18 days with typical symptoms of meningitis Her temperature kept about 100° F until just before death, when it rose to 109° There were no signs of tubercle (except, perhaps, a few crepitations at the right base) and the condition was diagnosed as cerebro spinal meningitis Lumbar puncture fluid was almost clear and contained but little albumin It showed few cells and numerous organisms similar to those seen in the two cases described above No cultures were taken

Necropsy —At the post mortem examination there were extensive tuberculosis of the lungs and mesenteric and abdominal glands and tuberculous meningitis The ears contained muco pus Cultures were made from the meningeal exudate and from the pus in the ears and gave numerous colonies of the organisms described above, together with a few colonies of yellow and white staphylococci This was a secondary mixed infection, probably from the middle ears

The above cases 1 and 2—fatal cases of basal meningitis in infants which have occurred recently in the Paddington Green Children's Hospital—are of peculiar interest in that they were associated with, and appeared to be due to, an organism quite unlike any known pathogenic bacterium, whilst in a third case, one of tuberculous meningitis, the same organism greatly predominated in a mixed infection which took place before death The above is a brief account of the clinical history and post mortem appearances of these cases I reserve a fuller account of the pathogenic organism for a future occasion when its characters have been more fully investigated The two cases in which this organism was present in pure culture in the exudate in the cerebral and spinal meninges, and in the pus which was present in the middle ears, occurred within three weeks of one another Both patients came from the West of London but not from the same district, and there was no reason to suspect a common source of contagion

In the three cases mentioned above we find the organism was isolated in cultures once during life from the cerebrospinal fluid and twice after death from the meningeal exudate and also from the pus from the middle ear It was seen in films from the lumbar puncture fluid, from the meningeal lymph or pus, and from the tympanic pus in all cases It seems fairly certain that it must be regarded as being the cause of the disease in the first two cases and as an important secondary infection in the third The association of pus in the middle ear in all three cases and the presence therein of the same organism as was found in the brain is of some interest in connexion with the etiology of the disease and of meningitis in general It is, of course, impossible to say whether the brain was infected from the ear or *vice versâ* A point in favour of the view that the ear became infected secondarily is the fact that in the first case no pain in the ear was noted until the day before death, whilst in the second case there was a discharge from the nose, suggesting another possible source of infection It is very unfortunate that this discharge was not examined bacteriologically In this case, too, it is noteworthy that there was no notice of any symptoms point-

branes were found to be normal On the other hand, in the few cases of septic meningitis following injury in which I have had an opportunity to examine the ears there has been no suppuration, suggesting that a purulent inflammation does not easily travel in that direction.

I have to thank Dr Guthrie and Dr Sutherland for permission to publish these cases, and Mr Holland and Mr Gilford, house physicians to the hospital who performed the lumbar punctures and provided me with the materials thus obtained

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

A CASE OF SURGICAL EMPHYSEMA AS A COMPLICATION OF DYSTOCIA

By WILLIAM M EMMERSON, L S A

THE patient in the following case was a primipara, aged 22 years, she was small but well built and well nourished and was in good health Labour commenced about 7 A M When I saw her at 9 A M labour pains had fairly set in, the membranes had ruptured and the size of the os was about that of a shilling Abdominal palpation established the fact of a head presentation but the position of the head could not be satisfactorily determined As the presenting part came within reach of the finger the mouth and nose were recognised, causing a face presentation to be diagnosed As the head was fixed, the pains good, and the pelvis fairly roomy I decided not to interfere with the presentation but leave the case to nature and two grains of pilula opii were administered At 7 P M the patient was in strong labour and the child's face was well down on the perineum Its *advance was now slow and the pains became violent*, birth taking place at 7 50 P M A few minutes prior to the birth the patient's appearance was normal, but immediately after the long and violent effort which expelled the fœtus her face was noticed to be much swollen and she complained of a choking sensation Her pulse was 110 per minute, weak but regular, and she was much exhausted I attributed the swelling to congestion, which I have before observed, but on the next day the face was still greatly swollen, as was also the neck the malar bones and prominence of the clavicles being obliterated She still complained of the choking sensation Palpation over the clavicles and bony parts of

On ex
the ribs
over the
note was normal all over There was no *bruit d'airain* or other sign of pneumothorax The pulse rate was still 110 and the temperature was 99 5° F The patient had slept fairly well and beyond the choking sensation there was no discomfort except slight shortness of breath The swelling and auscultatory phenomena gradually decreased and completely disappeared in four or five days' time With the exception of retention of urine, necessitating the use of the catheter for two days, convalescence was uneventful Careful subsequent examination of the chest revealed no alteration in the percussion note at the apices or elsewhere and no signs of tubercle The patient is now, after a lapse of two months, in her usual good health The condition was presumably due to rupture of air vesicles on one or both sides of the chest caused by the violent bearing down efforts, the air escaping into the neck at the root of the lung The patient was delivered of a stillborn fœtus with posterior hydrencephalocele and omphalocele

Hebburn on Tyne

A CASE OF EXTRAVASATION OF URINE

By THOMAS P CODD, L K Q C P, L R C S IREL

THE following case of extravasation of urine may interest some readers of THE LANCET

The patient was a man about 50 years of age who had for 21 years been suffering from traumatic stricture which occasionally caused retention of urine, but he was generally able to relieve himself by using a French bougie catheter No 4 He was a Spaniard and was once treated by a Greek medical man who told him when he could not pass urine to use a French bougie No 4 and after passing it down to the stricture to remove the stilet (if it did not pass through) and to let a little oil flow down through the catheter. He invariably passed it into the bladder, at the same time using it slowly and patiently. On July 13th, 1904, about 8 P.M. I was sent for and found him in bed with a number of pieces of absorbent wool saturated with arterial blood which was escaping from the urethra. He told me that while coming that afternoon from the North of Ireland in the train his bladder became over-distended and on getting out to pass urine he found himself at first unable to do so. He used all the force he could and felt something giving way; the urine then passed freely through the urethra and he obtained the greatest relief; blood afterwards came away and continued to escape for some hours until he sent for me. I prescribed rest and a mixture of ergot and opium, also ice to the perineum. On the next morning his wife sent word that the bleeding had stopped and that he had gone to business. He sent for me again in about ten days. I found him in bed with a quick, bounding pulse and a temperature of 101° F. The right testicle was swollen and tender. He told me that some years ago he had inflammation in the same testicle and had to apply three leeches which gave him relief. I did not care to use leeches, but I prescribed a lotion containing diluted solution of subacetate of lead which he applied for some days. On the inner side of the testicle a swelling came on gradually and eventually fluctuation could be felt. I recommended linseed poultices, not too large, which he kept on for a few days. I then made a free incision about an inch long in the scrotum whereupon watery fluid which had a very fetid odour gushed out, and after the opening was enlarged by Hilton's method there came out mixed blood and pus. I packed the wound with sal-alembroth absorbent gauze. On the next day the patient's temperature was 97° and his pulse-rate was 80; he had no difficulty in passing urine and felt quite comfortable. I syringed the wound daily with boric acid lotion and packed it with sal-alembroth absorbent gauze; it is now healing by granulation and the man has gone away for a change of air. I was surprised that the extravasation was not more extensive and that it came on so slowly.

This is an example of the danger of a patient forcing himself to pass urine when he is suffering from retention due to traumatic stricture and it might be of service for medical practitioners to caution patients in this respect. Happily such cases are rare, as this is only the second which I have seen after being in practice for 18 years.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

ST. GEORGE'S HOSPITAL.

A CASE OF EXCISION OF THE RECTUM FOR CARCINOMA; DEATH 21½ YEARS LATER FROM SECONDARY DEPOSITS IN THE LIVER.

(Under the care of Mr. C. T. DENT.)

THE following case is a very remarkable one owing to the extraordinarily long period of time in which malignant disease lay dormant after the operation of excision of the rectum. 21½ years of freedom from recurrence should be noted in these days of hopeless pessimism in cancer problems. For the notes of the case we are indebted to Mr. T. Crisp English, surgical registrar.

The patient was operated upon by Mr. C. T. Dent in 1882 for carcinoma of the rectum, and the following is an extract of the notes taken upon the case at the time.

The patient, a man, aged 52 years, was admitted into St. George's Hospital under the care of the late Mr. J. Rouse on August 18th, 1882. He stated that he had suffered from "piles" for about two years but had had no serious trouble until two months before admission, when he became subject to a continual desire to strain and to go to the closet; there was great pain after motions, especially when he was at all constipated, and he had passed small quantities of blood and slime. The pain and tenesmus had steadily become more severe and he was rapidly losing strength and flesh. On admission there were seen small external piles, and on the posterior wall of the rectum was a hard lobulated mass about one inch in diameter; blood and mucus came away on the examining finger; there was great pain, especially on sitting down. On Sept. 1st, Mr. Rouse examined the rectum under an anæsthetic and found extensive glandular carcinoma of the posterior wall, but the patient was so ill that it was thought inadvisable even to perform a colotomy. The pain was at first relieved somewhat by morphine suppositories but the tenesmus remained very troublesome, blood and mucus continued to discharge in large quantities, and finally the pain became very severe. On Nov. 8th a consultation was held and operation was decided upon in the hope of affording some relief to the patient's symptoms. On the followday therefore an anæsthetic was given and Mr. Dent made a careful examination of the rectum. A large, hard, and somewhat nodulated mass of malignant disease was found on the posterior and left aspect of the bowel just inside the anus; with the finger it was just possible to reach healthy bowel above. The growth was evidently of some thickness, extending deeply into the left ischio-rectal fossa. Mr. Dent then excised the rectum by the perineal route; an incision was made round the anus and gradually deepened until the bowel was completely detached from its connexions; the lower five inches were removed, the peritoneal cavity being opened in the process; attempts to draw the bowel down to the level of the skin proved unsuccessful. Hard nodular remnants were then dissected out of the ischio-rectal fossa. For a day or two after the operation the patient was in a critical state and then made a steady recovery. The wound healed well but a strong tendency to contraction of the anal orifice caused some trouble. This was successfully treated by the regular passage of bougies and division of constricting bands. The patient rapidly picked up his strength and gained flesh and was sent to the convalescent home on March 18th, 1883. The excised rectum was unfortunately not examined microscopically, but there can be no doubt that it was a case of malignant disease far advanced and much ulcerated.

On five occasions during the next 18 months the patient was readmitted into hospital for severe diarrhœa and evidence of ulceration of the large intestine; there was marked tenderness along the whole of the colon. On each occasion he was greatly benefited by voluminous injections of strong silver nitrate solution. Eventually this trouble ceased and he remained in excellent health until the end of 1903, having full control of solid fæces and partial control of liquid fæces. *A short time before Christmas*, however, he found himself becoming weaker and his medical attendant, Dr. F. B. Thornton, discovered enlargement of the liver; there was no jaundice, vomiting, or melæna.

On Jan. 29th, 1904, he was readmitted into the hospital, being now 74 years old; he appeared in fair health although rather wasted and pale, but considering his age he was wonderfully vigorous; he complained of no pain. The anus was represented by a deep funnel-shaped depression which appeared perfectly healthy. At the site of the union of the divided bowel to the surrounding parts was a sphincter-like constriction which admitted the forefinger fairly easily; there was slight prolapse, just extending down to the ring, of perfectly healthy mucous membrane. No trace whatever of disease was found in this region. In the abdomen the only disease that could be discovered appeared to be in the right lobe of the liver beneath the right rectus muscle; the liver was markedly enlarged, reaching to three fingers' breadth below the costal margin; its surface was hard and presented large nodules; there was no ascites. Both Sir Isambard Owen and Mr. Dent considered that the enlargement was undoubtedly malignant; the liver did not in any way appear like a cirrhotic liver. There were no indications for treatment and the patient returned home on Feb. 9th. On April 25th Dr. Thornton wrote to say that the patient had died with every evidence of secondary malignant metastases but that the relatives could not be induced to consent to a post-mortem examination.

Remarks by Mr. DENT.—The remarkable feature of this case is that the patient survived for 21½ years and then died from disease which, though it remained latent for so long a period, was, I think, undoubtedly secondary to, and directly connected with, the original mischief The possibility of a new primary malignant growth cannot, in the unfortunate absence of a post mortem examination, be wholly denied but there was no evidence whatever of any such lesion Duplay in an extensive collection of cases mentioned one of survival for 16½ years Volkmann records one in which death occurred eight years after operation from deposits in the liver without local recurrence Many instances of death from secondary malignant disease at long periods after removal of the breast for carcinoma have been recorded I have seen one such case in which death took place about 27 years after removal of the breast and I well remember another patient whom I saw about every three months after removal of the breast for scirrhous carcinoma 11 years after operation she seemed absolutely well but 12 *months later she died* from secondary malignant disease involving the sigmoid flexure, the form of secondary mischief that so often carries *off these patients In the face of such cases it seems* unwarrantable to talk of the curability of carcinoma or to fix an arbitrary time limit and to argue that patients who pass that limit are "cured " In the case above recorded the site of the operation was perfectly free from disease as far as could be judged The perineal operation in this instance appeared to have answered quite as well as the more modern methods of Kraske and Bardenheuer and the control of the fæces was quite satisfactory

Reviews and Notices of Books.

A Textbook of Legal Medicine and Toxicology Edited by FREDERICK PETERSON, M D , President of the New York State Commission in Lunacy, Clinical Professor of Psychiatry, Columbia University, New York, and WALTER S HAINES, M D , Professor of Chemistry Pharmacy, and Toxicology in Rush Medical College Chicago, Professorial Lecturer on Toxicology in the University of Chicago In two volumes London, Philadelphia, and New York W B Saunders and Co 1904 Vol II Pp 825 Price 21*s*

IN our review of the first volume of this textbook in THE LANCET of April 23rd, 1904, p 1128, we explained the general scope and nature of the work and expressed our opinion that it promised to be one of the best treatises on medical jurisprudence in the English language The second volume in every way maintains the high standard of its predecessor and the editors may rest well satisfied with the results of their labours

The first article is occupied with a consideration of Malingering *and the Feigned Disorders, by Dr J T Eskridge* and Dr Leonard Freeman The difficulties which beset the practitioner when he is called upon to differentiate between functional and organic disease are frequently great, still more so is this the case when possible fraud has to be contended with In former times surgical diseases were more frequently feigned than they are at the present day but attempted simulation of various nervous affections is common either to excite sympathy or to obtain damages after receiving injuries more or less severe such injuries being alleged to have been caused by the negligence of certain individuals The investigation of such cases calls for the greatest *circumspection on the part of the medical adviser* Especial stress is laid by the authors on feigned mental disorders, and the employment of tables comparing the symptoms in the true with those of the feigned disease considerably aids in drawing attention to the main points upon which a differential diagnosis may be made

The next contribution is on the legal aspects of pregnancy and is written by Dr W A Newman Dorland, who is also responsible for the following communication which is headed "Legitimacy, the Determination of Sex, Signs of Delivery " He carefully discusses many matters which are frequently the subjects of legal inquiry The vexed question of the duration of pregnancy naturally receives full attention Many notable cases have come before the courts in which it was of the utmost importance to the parties concerned to ascertain the extent to which pregnancy in the human female may be prolonged Unfortunately there is no time that can be stated as the positive duration of pregnancy Although about 280 days is generally accepted as the average, cases have been recorded in which this period has been considerably prolonged One authority, von Winckel, maintains that in about 11 per cent of pregnant women the duration of pregnancy is over 300 days, prolongation occurring from 302 to 322 days In some countries the limit is laid down by law but in England no period is fixed and the whole matter has to be argued before the court in every case in which the question arises In Dr Dorland's communication much interesting information on this subject will be found, in addition to remarks on the determination of sex and on various medico legal points connected with delivery

The article on Criminal Abortion by Dr E P Davis contains a full account of the methods which have been adopted to empty the pregnant uterus for an improper purpose and the symptoms and complications which may arise are accurately described Dr Davis also writes on infanticide As is well known, this crime is alarmingly frequent Moreover, it is a crime which is very difficult to prove It rests with the prosecution to show that the infant had had an independent existence for unless this can be done the prisoner *cannot be found guilty of murder The difficulties that may* arise in attempting to show that the child was born alive in the strictly legal sense are well described by Dr Davis Unfortunately, there is a great want of unanimity amongst legal authorities as to what determines "live birth ' consequently in many cases the prisoner is found *"not guilty ' of murder but is convicted on the charge of* concealment of birth A definite pronouncement based on medical rather than on legal grounds is earnestly to be desired

The contributions on impotence and sterility, rape and unnatural offences are by Dr C G Chaddock and are well *up to the general standard of the work in clearness and* completeness The articles on venereal and genito urinary diseases in their medico legal relations on marriage and divorce *on malpractice on the medico legal relations of* the Rontgen or x rays, and on laws relating to the insane will all be found of interest, although the last-named will be of more value to American than to English readers

The portion of the work dealing with toxicology is very full and complete It commences with an article on the General Principles of Toxicology by Dr W S Haines, in which directions are given for the detection and separation of poisons Inorganic poisons are described by Dr J W Holland The chemical properties of the various minerals and their salts are first considered and then follow the symptoms produced by a poisonous dose, the treatment to be adopted, the post mortem appearances, and the methods employed for the detection of the "noxious substances The chemical tests are particularly well given The organic poisons for purposes of description are divided into "alkaloidal and "non alkaloidal " The alkaloids are defined as the 'main poisonous principles of plants" and their properties are discussed by Dr A B Prescott The non alkaloidal organic poisons are considered by Dr Reid Hunt and Dr Walter Jones Under this heading are included the various forms of alcohol, chloral hydrate, chloroform, the coal tar series, and also preparations of various plants, *such as digitalis, ergot, aloes, colocynth,* pennyroyal, and many others

Dr C A Doremus describes the gaseous poisons, and an account of food poisoning is given by Dr. C. Harrington. Dr. V. C. Vaughan contributes a few remarks on Ptomaines and other Bacterial Products in their Relation to Toxicology. It has been stated that the chemical tests and especially the colour reactions for certain vegetable alkaloids may be simulated so closely by the products of certain bacteria that it becomes difficult, if not impossible, to distinguish with certainty between them. If this statement be true the possibility of mistaking putrefactive substances for vegetable alkaloids should always be borne in mind in making medico-legal investigations. Dr. Vaughan proceeds to discuss these difficulties in a very able manner, laying stress on the tests for morphine, conine, strychnine, atropine, and others. He also makes some extremely interesting observations on the Post-mortem Imbibition of Poisons. Within recent years the question of the diffusion of poisons through the dead body has acquired importance largely on account of the fact that arsenic, corrosive sublimate, and other poisonous substances are used for the purpose of embalming bodies. Obviously a poison may be introduced into the body after death for the purpose of preserving it or with the intention of casting suspicion upon an innocent person, or to suggest suicide as the mode of death. The body being examined, the poison is found in various organs, and the question arises as to whether it obtained admission before or after death. Dr. Vaughan quotes several cases where this doubt arose and the medical evidence was therefore of the utmost importance.

Taking the textbook as a whole, we can thoroughly endorse the favourable view we formed after a perusal of the first volume. It forms a most valuable source of reference in all matters connected with medical jurisprudence and toxicology.

Lehrbuch der Kinderheilkunde. (Textbook of the Diseases of Children.) By Dr. BERNHARD BENDIX. Third revised and enlarged edition, with 12 illustrations. Berlin and Vienna: Urban and Schwarzenberg. 1903. Pp. 604. Price 12*s.* 6*d.*

THIS volume is the third edition of a work which was originally written by the author as a contribution to the series of handbooks on the subject of hygiene edited by Professor Uffelmann; with the death of the latter hygienist some ten years ago this series of handbooks came to an end, but Dr. Bernhard Bendix provided for the continuation of the work by bringing it out in the form of an independent textbook on the diseases of children. And it is in this form, though revised and enlarged, that we now have an opportunity of reviewing his work. The double revision to which it has been subjected since it constituted a part of the system of hygiene has deprived it of its original and special characteristics and has reduced it or, perhaps, to speak more accurately, has extended it to the conventional and familiar proportions assumed by modern textbooks which comprise the whole subject of the diseases of children.

We find no fault with the general arrangement and handling of the various subjects dealt with in this volume. We cannot help thinking, however, that more recent French, English, and American contributions to the literature of pediatrics have hardly received the acknowledgment to which their importance entitles them. For instance, in the account of the artificial methods of infant feeding, although the percentage method is described, Dr. Rotch's work is not mentioned; this is surely a considerable omission. Indeed, the whole section, which is devoted to questions of nutrition, is hardly up to the general level of excellence which characterises the greater portion of the volume. This is the more unexpected because Dr. Bendix is a well-known authority on the diseases of infants due to nutritional disturbances. Moreover, he has conducted some very interesting investigations on the subject of the essential pathology of athrepsia or simple atrophy, a disorder which represents one of the most pronounced types of malnutrition. In the section in which he described this little-understood disease he supplies a short *résumé* of his own investigations. According to his observations in a series of cases of primary atrophy examined by him it was found that from 72 to 85 per cent. of the normal quantity of nitrogenous elements was absorbed and utilised and as regards the fatty elements of food something like 50 per cent. of the normal quantity was assimilated. Deficient absorption of nitrogenous and fatty elements of food is not, according to the author's views, a sufficient explanation of the cause of athrepsia, and though in all cases there is clearly a deficient absorption, nevertheless the deficiency does not adequately explain the essential features of the disease. On the other hand, he believes that we may find an explanation of the condition in an abnormally rapid tissue combustion due to the absorption of poisonous products generated in the alimentary canal. Rapid tissue combustion combined with a somewhat deficient absorption might explain the progressive loss of weight in these cases. With regard to the rational treatment of cases of athrepsia the author insists that on the assumption that a normal infant should receive the equivalent of 120 calories per kilogramme of body-weight per diem, an atrophic infant should be supplied with only the equivalent of 100 calories and that conformably with its deficient powers of fat absorption this element of the food should be proportionately limited. Valuable as theoretical considerations and generalisations of this kind undoubtedly are, it is perhaps open to question whether in particular cases any advantage is gained by measuring an infant's food in heat equivalents; the personal "index of nutrition" or "co-efficiency of utilisation" is necessarily a very important factor in determining the physiological food requirements of any infant. These indices cannot be arrived at on theoretical considerations, they can only be estimated by personal observation. In other words, clinical experience and clinical acumen are absolutely necessary for conducting the management of these cases.

Although the practical value of Dr. Bendix's book may be detracted from by too strict an observance of theoretical considerations, nevertheless for teaching purposes it is perhaps no matter for regret that he lays so much stress on the accuracy of figures. As compared with other textbooks of the diseases of children written in the German language this new edition of Dr. Bendix's work is far more in accordance with our own ideas of what the arrangements and scope of such works ought to be. It is a book which is easy to read and very convenient for rapid reference.

Clinical Lectures on Mental Diseases. By T. S. CLOUSTON, M.D., F.R.C.P. Edin., Physician Superintendent of the Royal Edinburgh Asylum for the Insane; Lecturer on Mental Diseases in the University of Edinburgh. Sixth edition. London: J. and A. Churchill. 1904. Pp. 738. Price 14*s.* net.

SCIENTIFIC views regarding mental disease have recently been undergoing great changes in regard to the etiology and evolution of insanity, the clinical standpoint and the classification which should be adopted in accordance with the modern developments of knowledge, and the whole question of the relationship of insanity to mental and physical degeneracy and deterioration. Pathology is slowly adding her quota of discoveries to the obscure problem of the morbid processes which affect the brain and nervous system, while the rôle of toxæmic agents and micro-organisms in the production of mental disorder is being recognised and studied more and more. Dr. Clouston's clinical lectures are intended to give the student a clear, concise, and graphic description of the typical forms and varieties of mental disease. *Beginning with a description of cases of melancholia* the various other psychoses are duly described—often in considerable detail as regards history and symptoms. The amount of information contained in these lectures is large and the mode of presentation of the clinical data is simple and suitable to the understanding of the beginner in psychological medicine. The older types and method of classification are adhered to throughout; this is, perhaps, inevitable in the sixth edition of a textbook of clinical lectures which embodies and reflects the teaching of 25 years ago. Since then, however, great strides and advances have been made and although in the preface generous acknowledgment is given to the remarkable achievements of the psychiatric school of Kraepelin and others, which has so profoundly influenced modern psychiatry, the standpoint and the spirit of the book reflect the old and not the new psychiatry. While this applies to the clinical portion of the work the pathological sections must be reserved for separate consideration. The character of the book as regards pathological drawings and reproductions of microphotographs has been considerably advanced. The number of plates amount to 29, and of these 22 are devoted to micro-photographs and drawings illustrating various changes in the brain and its membranes and vessels in mental disease. While a few of these are of a fair average level of mediocrity some show a high degree of excellence in definition and detail of the morbid structures involved. For several of the best illustrations Dr. Clouston acknowledges his indebtedness to Dr. W. Ford Robertson, pathologist to the Scottish asylums.

Referring more particularly to the clinical part of the work the subject of Paranoia receives scant and sketchy treatment. This important affection is not presented with anything like adequacy even of outline, no clinical record of cases is given, and the reading of the account leaves us with but a hazy impression of what the author is trying to convey. Dementia præcox of the katatonic form, which has been so thoroughly investigated in the last decade by the German, French, and American school, is regarded as a "variety of stupor," a singular harking back to the old views of half a century ago. The scattered remarks and criticisms of the views of Kraepelin throughout these lectures show that Dr. Clouston has not, we think, grasped the full significance of that worker's remarkable discoveries in clinical psychiatry.

Dr. Clouston's lectures on the whole reflect the spirit, methods, and ways of clinical psychiatry of 25 years ago. An attempt to bring it thoroughly abreast of modern knowledge and to imbue it with the new spirit would involve re-writing or the production of a wholly new work. But his lectures retain their value for their pleasant and interesting style of teaching after the manner of the older school of psychiatry.

English Medicine in the Anglo-Saxon Times: being the FitzPatrick Lectures for 1903, delivered before the Royal College of Physicians of London on June 23rd and 25th, 1903. By JOSEPH FRANK PAYNE, M.D. Oxon. Oxford: The Clarendon Press. 1904. Pp. viii.—162. Price 8*s*. 6*d*. net.

DR. PAYNE is well known as one of the most learned of our medical antiquarians and he has chosen for the first of the FitzPatrick lectures a period of great interest to all the inhabitants of these islands although one of which the records are but scanty. "The drums and tramplings" which swept over these unhappy islands during the eighth and ninth centuries destroyed most of the books stored in the libraries of the time, and the existing medical MSS. of the Anglo-Saxon period number only about 20. Of these the most important is the Leech Book of Bald. Besides this Dr. Payne deals with the Anglo-Saxon translation of the Herbarium Apuleii Platonici and the treatise Peri Didaxeon, *a translation into Anglo-Saxon from a Latin work by a* writer of the school of Salerno. The only existing MS. of this work belongs to about the middle of the twelfth century. Dr. Payne further discusses Anglo-Saxon surgery together with sundry charms and considers that some of these may have survived to the present day. Some 35 years ago there was a shrew ash in Richmond Park growing almost opposite to the cottage in which Sir Richard Owen resided and a medical man, who was then a boy at school in East Sheen, tells us that he had been told by cottagers in the district that it "was a good thing for children to pass them through the split in the trunk." As the superstition of the shrew ash is not generally known it may be as well to state that the shrew was formerly supposed to be exceedingly venomous for its bite, whether in cattle or men, gave rise to painful suppurating swellings. Various remedies were extant for these swellings but the most potent was a shrew ash. This was an ash tree in which a hole had been bored. A live shrew was placed in the hole and the hole was then plugged. The virtues or venom of the shrew then passed into the tree and by a species of homœopathy the touch of the tree cured the injuries inflicted by the shrew. A later development, of course, assigned curative properties for disease other than that conected with the shrew, and as far as our informant remembers the ash mentioned above was used for the cure of whooping-cough, the trunk of the tree having been split and the children being passed through the cleft.

Dr. Payne's lectures may be confidently recommended to all those members of our profession who take an interest in the early history of their art, and the illustrations, which are reproductions of drawings by Miss E. A. Ibbs, give an additional charm to his work. The originals are to be found in various MSS. in the British Museum and are mostly from the Anglo-Saxon translation of the Herbarium of Apuleius.

LIBRARY TABLE.

Transactions of the Grant College Medical Society, Bombay from February, 1903, to March, 1904.—The report of a paper read by Dr. Raghavendra Row on the Serum Reaction of Bacillus Pestis in Plague, studied in the light of recent researches on immunity, makes interesting reading. He summarises as follows: 1. The lysogenic action of plague convalescent's blood on bacillus pestis is brought about by the combined action of two distinct bodies: (*a*) one of the nature of amboceptor (not destroyed by heat up to 56° C.); and (*b*) the other of the nature of complement (destroyed at 56° C.). 2. A serum from a plague convalescent loses its lysogenic action on bacillus pestis by age and exposure to light in a few days and in a few minutes by exposure to 56° C. (probably due to the destruction of complement). 3 This lost property is restored by a mixture of a fresh serum—e.g., from the rabbit (addition of complement). 4. Rabbits when suitably immunised to plague produce a serum rich in precipitins and containing a fair amount of bacteriolysin (to bacillus pestis). 5. By exposure to heat of 56° C. the bacteriolysin is rendered impotent (owing to destruction of complement); it is, however, to a certain extent restored by addition of fresh rabbit's blood serum (complement). 6. Roux's antipesteux serum is very rich in precipitin but not particularly bacteriolytic to bacillus pestis as such. 7. This loss of bacteriolytic property is probably due to age and is certainly produced by exposure to 56° C. (owing probably to loss of complement). 8. By addition of fresh rabbit's, man's, rat's, &c., fresh serum, however, the bacteriolytic property is restored (fresh complement). 9. Blood serum of patients dying from plague is deficient in amboceptor and its complement is not only poor but of the nature of an anti-complement. At the August and November meetings of the same society Dr. K. M. Dubash read papers on a case of Abdominal Section for Ruptured Uterus and on Some Causes of Sterility and Some Points in its Cure in Women. In the former paper he drew special attention to the administration of ergot by midwives, dwelling on the disadvantages and risks of its administration until after the expulsion not only of the child but also of the placenta.

Nos. 3, 4, and 5 of the first volume of the "Calcutta Practitioner."—In the *Calcutta Practitioner* (March 1904), Dr. Gopal Chandra Chatterji, assistant bacteriologist, Pathological Laboratory, Calcutta Medical College, has a paper entitled "Some Researches on the Malaria Parasite and its Intermediary Host—the Anopheles." They are arranged as follows: (*a*) description of the several varieties of malaria parasites (with short notes of some cases in which they were found); (*b*) special study of flagellation of malignant tertian parasite in view of the recent theories put forward by Major A. Buchanan, I.M.S.; and (*c*) description of the varieties of anopheles found in and about Calcutta with an attempt to find out the malaria-bearing ones. In the same number is a good notice of the life of the well-known native scientist, Dr. Mahendra Lal Sircar, the founder of the Science Association in Calcutta and an eminent member of the University of Calcutta. The April number contains some interesting notes on Hydnocarpus Oil in Diabetes, Rheumatism, Chronic Skin Diseases, and Leprosy, by Dr. Hem Chandra Sen, teacher of materia medica, Campbell Medical School, Calcutta. This oil is one of the oldest known remedies employed as a domestic medicine by the natives. The writer says there is no remedy superior to it in the treatment of leprosy. In this issue and in the May number Dr. Suresh Chandra Bhattacharya, first demonstrator of anatomy, Medical College, Calcutta, has good papers on Some Obscure Forms of Joint Diseases and Diseases in the Neighbourhood of Joints.

Analytical Records

FROM

THE LANCET LABORATORY.

DIGITALONE.

(MESSRS. PARKE, DAVIS, AND CO., 111, QUEEN VICTORIA-STREET, LONDON, E.C.)

DIGITALONE is a clear brown fluid containing all the active principles of digitalis. Its strength is equal to one-tenth that of the fluid extract of digitalis or four-fifths that of the tincture, the hypodermic dose being from eight to 15 minims. Digitalone is aseptic and non-alcoholic but its most important property is that it is non-irritating and therefore is specially adapted for hypodermic use, whereas ordinary preparations of digitalis are not suitable for this purpose on account of the presence of spirit and extractives. Digitalone is adjusted to a definite standard by physiological assay.

KOLJE.

(MR. J. GRANT GLASS, 123, GILMORE-PLACE, EDINBURGH.)

Kolje is described as a peptonised pure calves'-feet jelly, prepared with extract of kola nut and other ingredients. Our analytical examination confirmed this description, as we found peptones to be abundant, while a small quantity of the alkaloid caffeine was successfully extracted. Analysis gave the following results: water, 83·64 per cent.; and solid matters, 16·36 per cent., including 0·33 per cent. of mineral matter. About three-fourths of the total solid matter consisted of peptonised albuminoid. There were indications of boric acid. The solid portions of "Kolje" are doubtless nutritious as well as stimulating but the relatively large amount of water obviously reduces the nutrient value of the preparation, considered in its entirety.

ARDENNESE MILK AND CREAM.

(HEYMANN, FRÈRES AND CO., BRUSSELS. AGENCY: JOEST VAN HEEL AND CO., 3, DENMAN-STREET, LONDON BRIDGE, S.E.)

These milk products are manufactured at Lamarcheville, near Chimay, Belgium. They both gave satisfactory results on analysis which proved also that they were free from preservatives. Moreover, the sterilising process employed evidently interferes very little with the natural flavour. The milk gave the following results on analysis: total solids, 12·24 per cent.; fat, 4·14 per cent.; and mineral matter, 0·82 per cent. This is good rich milk. The cream gave the following results: water, 56·91 per cent.; and total solids, 43·09 per cent. The latter consisted of fat, 36·74 per cent.; curd, &c., 5·96 per cent.; and mineral matter, 0·39 per cent. The cream possessed a good flavour and, as is evident, shows on analysis excellent qualities.

NEW "TABLOIDS," "SOLOIDS," AND OTHER PREPARATIONS.

(MESSRS. BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

Amongst new additions to the list of tabloids which we have recently received are the tabloid glycerophosphates compound containing the combined glycerophosphates of calcium, sodium, potassium, magnesium, and iron, with pepsine, diastase, ignitia, and kola equivalent to half a fluid drachm of syrup of glycerophosphates; tabloid ophthalmic of zinc sulphate and cocaine hydrochloride for use as a painless astringent in ophthalmic practice; and tabloid of iron and strychnine phosphates, each containing one grain of phosphate of iron and $\frac{1}{12}$nd of a grain of phosphate of strychnine. A very useful new "soloid" is that containing the double salt of iodide of mercury and potassium. It is an excellent means of securing the effects of mercury biniodide in solution. The soloid dissolves readily in water, yielding a reddish fluorescent solution which is sufficient to indicate the presence of a poison. We have received also specimens of the following preparations: morphine phosphate, described as a soluble, stable, and trustworthy salt which is preferable to the acetate; guaiacol camphorate, an acid salt of guaiacol and camphoric acid, used with favourable results in phthisis (the salt passes through the stomach without change and without gastric disturbance but in the alkaline secretions of the intestine guaiacol is liberated under conditions obviously favourable for its absorption); calcium hypophosphite, a readily soluble salt in water; and, lastly, podophyllin, prepared strictly in accordance with the official method from a carefully selected drug. This is practically soluble in 90 per cent. of alcohol and yields only one-fourth the amount of ash laid down in the B.P. test.

SCOTCH WHISKIES.

(MESSRS. GREENLEES BROTHERS, GLASGOW, AND 29 TO 31, COMMERCIAL-STREET, LONDON, E.)

We believe these whiskies to be described correctly and evidence is not wanting that they are well matured. We have taken for analysis four types selected from a list containing ten different descriptions of whisky. Lorne Highland whisky gave the following results on analysis: alcohol, by weight 42·29 per cent., by volume 49·81 per cent., equal to proof spirit 87·29 per cent.; extractives, 0·30 per cent.; and mineral matter a trace. The secondary products were as follows, given in grammes per 100 litres of alcohol present: acidity reckoned as acetic acid, 31·20; aldehyde, 25·00; furfural, 1·50; ethers reckoned as ethyl acetate, 38·72; and higher alcohols, 240·00. The feature of this analysis is that the furfural is decidedly lower than in many all-malt whiskies and the same observation applies to the proportion of ethers. The G. B. Special Scotch whisky gave the following results on analysis: alcohol, by weight 39·30 per cent., by volume 46·59 per cent, equal to proof spirit 81 64 per cent, extractives, 0 13 per cent, and mineral matter, *nil* The secondary products were as follows, given in grammes per 100 litres of absolute alcohol present acidity reckoned as acetic acid, 60 00, aldehyde, 18 00, furfural, 3 55, ethers reckoned as ethyl acetate, 41 20, and higher alcohols, 160 00 This is an excellent, well matured all malt whisky Antique Pure Highland whisky gave the following results on analysis alcohol, by weight 41 80 per cent, by volume 49 29 per cent, equal to proof spirit 86 37 per cent, extractives, 0 19 per cent, and mineral matter, a trace The secondary products were as follows given in grammes per 100 litres of absolute alcohol present acidity reckoned as acetic acid, 46 00, aldehyde, 50 00, furfural, 3 00, ethers reckoned as ethyl acetate, 100 00, and higher alcohols, 160 00 The feature of this analysis is the high proportion of ethers and in this respect the spirit equals brandy The result is evidence in favour of the whisky being accurately described as "antique" Claymore whisky gave the following results on analysis alcohol, by weight 41 80 per cent, by volume 49 29 per cent, equal to proof spirit 86 37 per cent, extractives, 0 14 per cent, and mineral matter, *nil* The secondary products, given in grammes per 100 litres of absolute alcohol present, were as follows acidity reckoned as acetic acid, 31 20, aldehyde, 20 00, furfural, 1 80, ethers reckoned as ethyl acetate, 38 72, and higher alcohols, 140 00 These results do not coincide with those usually given by a spirit made exclusively from barley malt It is, however, a whisky with a "clean" and delicate flavour All these whiskies give evidence of being carefully prepared from good materials and they are pure in the sense that they are of good potable quality

BRAX BREAD AND FLOUR

(BRAX LIMITED NEEDHAM MARKET, SUFFOLK)

Brax bread is a malted bread and therefore much of the starch has been reduced to a soluble condition It contains further a very satisfactory proportion of proteids, amounting in the dry substance to 12 72 per cent The mineral matter amounted to 0 78 per cent Similarly Brax flour proved to contain 13 33 per cent and 0 65 per cent of proteid and mineral matter respectively The bread has an excellent flavour and it readily yields to the action of digestive ferments The microscope showed the practical absence of the irritating insoluble matters of wheat flour The bread keeps moist and in good condition for several days longer than does the ordinary white loaf

THE AIX LA CHAPELLE NATURAL PRODUCTS

(THE AIX LA CHAPELLE NATURAL SPRING PRODUCTS LIMITED AGENCY 24 AND 26 BASINGHALL STREET, LONDON E C)

The chief constituents of the Aix la Chapelle water are chloride of sodium and carbonate of sodium, whilst amongst the more important subsidiary constituents should be mentioned sulphide of sodium with traces of bromide and iodide of the same metal Our analysis of the Aix la Chapelle natural water practically confirms the analysis which is officially published in Germany We found the total saline contents to be 3 63 grammes per litre consisting in the dried residue of 2 86 grammes of common salt, 0 637 gramme of carbonate of soda, and 0 133 gramme of calcium carbonate We have also examined specimens of bath salt and drinking salt obtained by the evaporation of the natural water These are identical in composition with the salts contained in solution in the sample of water submitted to us The salts consist, that is to say, of about three fourths common salt and one fourth carbonate of soda It is suggested that by means of these salts equally beneficial results can be obtained by home treatment and therefore the journey to Aix la Chapelle can be dispensed with It may be pointed out, however, that much of the benefit derived by taking a course of waters is due to the rest, change, and regular living which such a régime involves Lastly, we have examined a specimen of soap containing a small proportion of the salts of Aix la Chapelle We fail to see what advantage is obtained by mixing soap with a little bicarbonate of soda and salt, especially as the sulphides present in the natural water do not exist as such in the soap or in the evaporated salt but as sulphates. Sulphides in soap might possibly have a beneficial action on the skin

PROVOST OAT BISCUIT

(GRAY DUNN AND CO KINNING PARK, GLASGOW)

The oat is regarded as the most nutritious of all cereals. According to our analysis this biscuit contains 14 17 per cent of proteid, which is about the maximum that oats give on analysis The mineral matter amounted to 2 62 per cent The biscuit is well made and possesses an excellent oaten flavour It may be observed also that the oat contains nearly 10 per cent of fat which, however, tends to become rancid This objectionable tendency is apparently checked in the provost oat biscuit, as the flavour of the oat in it is preserved fresh.

MILO FOOD

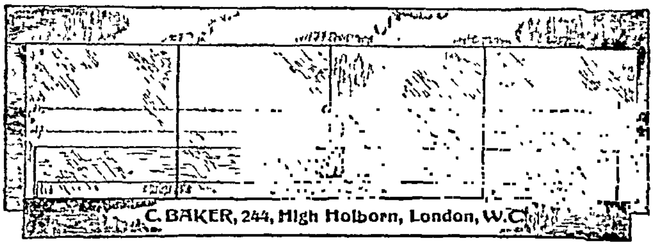
(HENRY NESTLE 48 CANNON STREET AND 49 QUEEN VICTORIA STREET E C)

According to our analysis this is a malted cereal food with a basis of milk Analysis shows a small proportion of unaltered starch, the carbohydrates consisting for the most part of malt sugar, milk sugar, cane sugar (added), and dextrin The extent to which milk enters into the composition of the food may be judged from the total amount of proteid and of fat present According to our analysis the former amounted to 14 08 per cent, in the latter to 7 00 per cent 67 per cent of the food proved to be soluble in cold water Mineral matter amounted to 1 20 per cent. The preparation presents all the elements necessary in infant diet and the constituents are together in desirable proportion except, perhaps that the percentage of fat might be increased with advantage and the carbohydrates spared in corresponding proportion The food is very palatable and very readily prepared

New Inventions.

ALL METAL COVER GLASS HOLDER

DUE to the use of wood in their composition, some cover glass holders offered for sale are liable to warp in hot climates, others are limited in their usefulness, being made to receive but one size cover glass, while in another the worker is prevented from placing his specimens in an oven owing to the employment of indiarubber in its construction In consequence of these drawbacks of other frames I have designed an *all metal* holder capable of receiving any size cover glasses between 15 and 26 millimetres, a sufficient range, probably, to meet the requirements of all workers *It has the following* advantages (1) it will receive glass covers of any size in general use, (2) being made entirely of metal it can be easily washed or sterilised, and (3) specimens requiring heat can be placed in an oven with the films in position without fear of ruining the holder Square or oblong cover glasses are recommended Having used a cover glass holder for some years I can endorse Major D G Marshall's remarks in THE LANCET of May 7th, 1904 p 1288, as to the general advantages of such an instrument when making blood films—viz, no time is wasted choosing and picking up cover glasses, [illegible] fingered When prepared [illegible] paper or dropped into a sn[illegible] the films by dust, &c, being thus avoided The following are the directions for use With the holder between the finger and thumb of the left hand the sliding bar is pulled with the right until the opening is a little wider than necessary The cover glasses are placed on the base plate, the sliding bar is brought into apposition with the covers, and the holder is prepared for taking a "spread." A small projecting pin at the end of the plate secures the covers from sliding off. The groove along the centre of the base-plate will enable the operator to remove the cover-glasses easily by means of forceps.



Messrs. C. Baker of 244, High Holborn, London, W.C., supply the holder.

Pakhoi, South China. Edward Horder, F.R.C.S. Edin.

ASYLUM REPORTS.

Royal Edinburgh Asylum (Annual Report for 1903).—The average number of patients resident during the year was 917, comprising 460 males and 457 females. The admissions during the year amounted to 411—viz., 196 males and 215 females. Of these 334 were first admissions. Dr. T. S. Clouston, the medical superintendent, states in his report that the number of admissions was large and it would have been much larger had it been possible to admit those who applied as private patients at the lower rates of board. Looking at the admissions generally "from a medical point of view there was an unusual number of aged and broken-down people—one patriarch was 98. There was a very large number of cases suffering from general paralysis ...... and the number of alcoholics was *excessive to a degree unprecedented in our history.*" The number of patients discharged as recovered during the year amounted to 145—viz., 67 males and 78 females, or 15·8 per cent. of the average number resident. The deaths during the year amounted to 119, or 13 per cent. as calculated on the same basis. Of the deaths four were due to cardiac disease, eight each to cerebral hæmorrhage and pneumonia, 16 to pulmonary and other forms of tuberculosis, 23 to senile decay, 38 to general paralysis of the insane, and the rest to other causes. Reviewing the history of the last three decades in the work of the Royal Edinburgh Asylum, Dr. Clouston states that in the year 1873 there were 583 pauper patients in the asylum chargeable to Edinburgh and Leith. This was a proportion of cases of lunacy of 1 to every 413 of the general population of this area. In 1883 the proportion of lunatics continued at 1 to 413. In the year 1893 there were 877 patients drawn from the same area, or 1 to 379 of the population, and in 1903 the number of patients was 1248, or 1 to every 315 of the population. For the whole of Scotland the proportion of the lunacy population to the general population was 1 to 371 in 1893 and 1 to 320 in 1903. The increase of lunacy during the last three decades is partly, says Dr. Clouston, due to an increase of certain forms of mental disease, such as general paralysis and alcoholic insanity, and to the increasing facility with which the public avail themselves at the present day of asylum care and treatment. In the five years 1873 to 1877 the percentage of alcoholic cases in the asylum was 18·5 for males and 10·4 per cent. for females; it has steadily gone up and now it has doubled. No explanation will account for this, says Dr. Clouston, but the one that certain classes of our population are drinking to greater excess than they did, and in doing so are, many of them, destroying their sanity. ...... This is also confirmed by the increased drink bill of the empire and the increasing police arrests for the smaller offences connected with drunkenness." The Commissioners in Lunacy report very favourably on the administration of the asylum and on the care and attention bestowed on the inmates.

West Sussex County Asylum, Chichester (Annual Report for 1903).—The average number of patients resident during *the year was 695, comprising 306 males and 389 females.* The admissions during the year amounted to 151—viz., 75 males and 76 females. Of these, 123 were first admissions. Mr. H. A. Kidd, the medical superintendent, states in his report that a number of applications for the admission of private patients have had to be declined owing to the lack of special accommodation. The admissions during the year were of a distinctly unfavourable character, only one-fifth of the whole number being deemed recoverable. Four males and five females were actively suicidal on admission. Hereditary predisposition to insanity was ascertained to exist in 42 per cent. of the cases and was present in half the cases in which any history at all was obtainable. One-fourth of the admissions had had previous attacks of insanity. These two causes, says Mr. Kidd, "constitute the predisposing factors of attack. The precipitating factors include the so-called moral causes, assigned in 20 cases, and the physical causes, of which the principal are alcoholic excess (24 cases), senile decay (15 cases), and epilepsy (11 cases)." Congenital mental deficiency was present in 13 admissions. The number of patients discharged as recovered during the year amounted to 47—viz., 24 males and 23 females, or 6·8 per cent. of the average number resident. The deaths during the year amounted to *59, or 8·5 per cent. as calculated on the same basis.* Of the deaths one was due to senile decay, two each were due to epilepsy and cerebral hæmorrhage, five each to cancer and general paralysis, six to cardiac disease, ten to pulmonary and other forms of tuberculosis, 22 to organic disease of the brain, and the rest to other causes. Necropsies were made in all cases of death but three. Two inquests were held during the year—the first, on June 5th, upon a senile dement who sustained an accidental fracture of the ribs and died from subsequent pneumonia, and the second, on Oct. 22nd, upon a suicidal patient, a man who was admitted with a seriously cut throat, from the effects of which he died eight days afterwards. With the exception of a severe epidemic of influenza during the early months of the year the general health of the patients and staff had been good. The epidemic of influenza affected 100 patients and though not so extensive as last year (when the number of patients affected was about 200) it was of a serious nature and caused two deaths. "The epidemic was at first of the gastro-intestinal type, and having regard to this and to its origin amongst the farm staff it was considered necessary to sterilise all the milk-supply. This had a good effect, for the epidemic abated and the type of subsequent cases was of the ordinary myalgic character." The Commissioners in Lunacy state in their report that the asylum was found to be maintained throughout in the best of order, that the day-rooms were bright and comfortable in appearance and plentifully supplied with flowers and objects of interest, that the condition of the dormitories and bedding was quite satisfactory, and that the patients were neat, tidy, and well behaved. The committee of management states in its report that improvements are being carried out in the laundry department and that increased provision for dealing with outbreaks of fire has been made. Additional means of exit in case of fire have also been provided for the nurses' block.

North Devon Infirmary, Barnstaple.—The annual meeting of the governors of this institution was held on August 16th. The medical report stated that 840 in-patients were admitted during 1903, against 668 in 1902, while the out-patients numbered 3032 against 2541 in the previous year. The financial statement showed that the expenditure had exceeded the income by £525, £1057 had been received from legacies, and the Hospital Sunday collections amounted to £370, being slightly less than in the preceding year.

Vaccination Statistics.—At the meeting of the Bristol board of guardians held on August 13th it was reported that 4575 births were registered from July to December, 1903, and that of these children 2890 were successfully vaccinated, 106 had exemption certificates, and 16 were insusceptible to vaccination.—At the meeting of the Axbridge (Somerset) board of guardians held on August 16th it was stated that 490 births were registered in the districts of the union during the half-year ended December, 1903, and that of these children 289 were successfully vaccinated, *98 had exemption certificates,* and one was insusceptible to vaccination.

THE
BRITISH MEDICAL ASSOCIATION.
MEETING AT OXFORD

THE SECTIONS.
PSYCHOLOGICAL MEDICINE
FRIDAY JULY 29TH

Mr CONOLLY NORMAN (Richmond District Asylum, Dublin) read a paper on

Dementia Præcox, or the Premature Dementia of Adolescents

The existence, he said, of a single large and distinctive group of mental diseases which comprised three such varying and different mental disorders as those known under the names of hebephrenia, katatonia, and paranoid dementia præcox could be only admitted under conditions that satisfied modern tests as to what constituted disease The only connecting links added Mr Norman, which existed among these three affections named were their origin and occurrence at the age of puberty and adolescence (between the fifteenth and the twenty fifth years of life) and their decided tendency to early termination in dementia With *regard, however, to their origin at the epoch of puberty* and adolescence the peculiarities exhibited by these three insanities were largely explicable as exaggerations and morbid perversions of psychological characteristics and tendencies proper to this epoch of life, modified or distorted by disease As regards the alleged early and strong tendency to dementia in these cases the statement was, said Mr Norman, open to correction, since a considerable minority of cases of so called dementia præcox recovered Moreover, no definite or distinct organic degenerative changes, he continued, had been demonstrated post mortem in cases of dementia præcox, the changes described by a few authors (to whom he referred) being of a casual nature and even hypothetical No thorough investigation, based on modern methods of histological technique, had been made on the pathology of dementia præcox and until such evidence was forthcoming it was well to hold their judgment in suspension and to cease from applying to it the term dementia It was, however, he urged, true that adolescent cases of insanity not recovering had a special liability to run into a peculiar form of dementia In cases of dementia præcox there was an incoordination or "ataxy" of the mind, not a paresis or paralysis such as occurred in the case of general paralysis and which alone deserved the name of true dementia The dementia of adolescent insanity supervened at the termination of an attack or attacks of mental disorder of very *varying character, marked by phases and mixed conditions* of excitement, shallow depression, cataleptiform attitudes and poses, stuporous attacks with negativism and resistiveness to everything required to be done by the patient, and other symptoms indicating the occurrence of hallucinatory mental confusion Therefore, he said, dementia was a faulty term to apply to cases of this class Moreover, to call anything precocious because it occurred in early life "was a perversion of terms, for precocious implied too early arrival at an inevitable end Moreover, the curability of a small percentage of cases of dementia præcox forbade them to use the term dementia—a name which encouraged despair The term insanity of adolescence was free from such objection, it committed them to no views of its prognosis and was therefore the more suitable word to use In saying this he did not wish to disparage the splendid work done by various psychiatrists of France, Germany, and America but he could not (while admitting their facts and descriptions) accept everything in their terminology

Dr W R DAWSON (Dublin) considered it undesirable to group the diseases in question under the term dementia præcox since hebephrenia was often a curable affection, and in view of the age of some cases the term præcox could not be applied as the equivalent of "youthful" He thought that a simple classification solely for teaching purposes was the only admissible one—a classification like that of the time honoured scheme which divided mental diseases into mania, melancholia,
dementia. The absenc
logy of dementia præco.

or refusing at present to accept, its claims as a nosological entity

Dr ERNEST W WHITE (City of London Asylum, Dartford) preferred the term "premature dementia" as a title for the mental decadence occurring between the limits of puberty and adolescence During the last few years their terminology had been so saturated by the fertile brains of the continent that there was a plethora of titles He had seen many cases of premature dementia, both of the so called paranoic and hebephrenic varieties, during the past ten years among the better educated and highly strung patients of the "private" class, whereas among the pauper or rate paid class of patients this affection was less common and in asylums which drew their inmates from agricultural districts such cases were rarer still

Dr W KONIG (Berlin) stated that his clinical experience was in harmony with that of Dr White There was undoubtedly a distinct class of cases which could be conveniently termed dementia præcox Some of these were congenitally weak minded, a greater percentage, however, exhibited a normal ng the
prognosis he never ver before
one or two years of he had
never seen a case permanently recover

Dr DAVID BOWER (Bedford) expressed general agreement with the views of the previous speakers He regretted that nothing had as yet been discovered to make the diagnosis of the disease certain until incurability set in from lapse of time

Dr G E SHUTTLEWORTH (Richmond) said that dementia præcox was very rare in the class of patients—feeble minded children under the London County Council—with which he had to deal, he had met only a single case which exhibited the classical symptoms of hebephrenia and who was a member of a highly neurotic family He agreed with what was laid down by the late Dr Langdon Down, that such cases exhibited an innate tendency to mental defect and deterioration at the developmental or adolescent period of life

Dr W LLOYD ANDRIEZEN (London) said that on the whole he supported the use of the term dementia præcox, understanding by it the premature dementia which occurred in pubescence and adolescence, which was typical of that epoch of life and which had a definite basis of dementia on which were variously superposed disturbances of the nature of mental confusion and hallucinations While having remote affinities with recurrent mania and still more remote affinities with paranoia it was conducive to clearness of ideas and, indeed, consonant with facts of clinical and general psychiatry to keep the class of dementia præcox by itself Although externally rather ill-defined (and what group of insanity had not "straggling" cases resembling neighbouring groups?) the cases of dementia præcox aggregated well and distinctively under five "centres of condensation, so to speak, he thus recognised a simple, a hebephrenic a katatonic, a paranoid and a criminal form of dementia præcox, but he would not refer in detail to these as he had made that the subject of a paper published by himself about a year ago

Dr T SEYMOUR TUKE (London) said that he could not accept the term dementia præcox though he accepted the group of diseases which it connoted He preferred the term adolescent insanity

Dr E S PASMORE (Croydon Asylum) accepted the use of the term dementia præcox as concise and convenient, and said that although in a sense it was used to hide their ignorance no better term was before them He had often found on inquiry into the history of cases that they had suffered earlier in life from "fits" and obscure attacks of nervous excitement or breakdown, and hoped that in time they would discover the physical basis of this disease

A paper was then read by Dr PASMORE on

How to Take a Family History

The paper pointed out the kind of details and data to be collected so that the physician could tabulate in the form of a diagram a record of the mental state of the ancestors, descendants, and collaterals of the patient At present, he said, there was not in our public asylums any regular system or rule by which an accurate and trustworthy family history could be taken The diagrams which he had drawn up for his own studies and which he passed round showed clearly how this could be done The family history for three generations could thus be given in the diagram, but, said

Dr. Pasmore, it was useless to enlarge the scope of this aspect of the diagram since history of a trustworthy character could not be obtained beyond three generations.

Dr. A. T. SCHOFIELD (London) read a paper on

The Cure of Quackery.

The quack, he said, flourished in every land where he was safe from the law so long as he did not infringe the technical part—the "letter," so to speak—of the law. The gullibility of human beings and the hope which sprang "eternal in the human breast" were two chords on which the quack played. Quacks cultivated methods and means of treatment which made a deep impression on ignorant persons; they cultivated and exercised also their powers of mental "suggestion" on patients. He thought that physicians should themselves pay greater attention to the mental factor in disease and, above all, to the operations, obscure, it was true, but nevertheless potent, of the "unconscious mind" in helping the cure of disease.

A few brief remarks from Dr. F. W. EDRIDGE-GREEN (London), Mr. JAMES STEWART (Bristol), and Mr. G. STEVENS POPE (Middlesbrough) followed the paper, after which the proceedings were brought to a close.

LARYNGOLOGY AND OTOLOGY.

THURSDAY, JULY 28TH.

A discussion on

The Etiology, Treatment, and Prognosis of Innocent Growths of the Larynx

was opened by Dr. J. DUNDAS GRANT (London) and Professor A. ROSENBERG (Berlin).

Dr. DUNDAS GRANT in opening the subject limited himself to non-malignant growths found in the interior of the larynx. Many growths in the larynx, he said, were so closely related to inflammatory products that they could not be distinguished from them and, indeed, were identical with them in their anatomical structure. Their diversity depended mainly upon which elements in the composite structure of the laryngeal mucous membrane were chiefly affected. Amongst the commonest growths in the larynx were found papillomata (pachydermia verrucosa) essentially identical with the pachydermia found in its most typical forms on the vocal processes and in the interarytenoid space. Such growths as fibromata, fibro-papillomata, fibro-adenomata, cysts, and angeiomata were also explicable as the result of inflammatory conditions. Those parts of the vocal cord which underwent the greatest amount of mutual concussion and attrition, such as the junction of the anterior and middle thirds (the most frequent nodal point during phonation), the vocal processes, and the interarytenoid space, would seem to be most liable to chronic inflammatory and neoplastic changes. In the interarytenoid space the result was a diffuse thickening (pachydermia) at the vocal process (the typical pachydermic nodule). At the junction of the anterior and middle thirds of the cords there might be a "singer's nodule" consisting of a simple epithelial thickening (a miniature corn), a smaller or larger papilloma generally of soft consistence, or a sessile or pendulous œdematous fibroma which might exceptionally contain glandular structure. The chief causes of irritation of the larynx were over-use, or wrong use, of the voice and irritating vapours or dusty atmosphere; excess in tobacco smoke (especially inhalation of cigarette smoke) might also be quoted. Nasal obstruction leading to mouth breathing or purulent nasal discharges inhaled into the larynx were among the most potent contributories. Speaking of the prognosis of innocent laryngeal growths, Dr. Grant said that was dependent mainly upon their accessibility for removal and the possibility of avoidance of the predisposing and exciting causes. If not removed their tendency was to increase of growth, leading to fatal obstruction to respiration. Spontaneous disappearance was possible in the case of papillomata but could not be counted upon. After operation recurrence was possible unless the removal was complete. Dr. Grant's experience led him to the view that single pedunculated growths at the anterior commissure were unlikely to recur, whereas sessile ones at the junction of the anterior and middle thirds of the vocal cord were very likely to do so, as also were multiple papillomata. The question of malignant transformation of benign growths, he said, could not be left unconsidered. Practically it only arose in connexion with papillomata which, in exposed parts of the body, had a tendency under repeated or continued irritation to develop into epitheliomata. There was no reason for immunity on the part of the larynx, but the result of Semon's collective investigation seemed convincing as to its extreme rarity. Speaking of the treatment Dr. Grant said that this was not necessarily always operative. The avoidance of exciting and predisposing causes—for example, complete silence or limitation of the voice to a whisper for several months—was sometimes sufficient in cases of very small nodules due to over-use or misuse of the voice. In other growths removal was the only treatment and it should be carried out *per vias naturales*. The form of instrument employed varied with the special experience of the operator. For the destruction of the stump various caustics had been employed, such as nitrate of silver, formalin, chromic acid, tri-chloracetic or salicylic acid; the last-named was, in Dr. Grant's opinion, particularly valuable for papillomata. Recent experience had impressed him very favourably with the value and practicability of the fine galvano-cautery point. The distance from the dorsum of the tongue to the vocal cord was sometimes very considerable and beyond the reach of ordinary laryngeal forceps—fully four inches. In such a case he had eradicated a papilloma of the size of a split pea by a few touches of the fine galvano-cautery point. In considering the question whether any circumstances would call for removal of non-malignant intralaryngeal growths by external operation, Dr. Grant said that certainly the cases in which it was justifiable were extremely few with growths on the inner aspect of the framework of the larynx. When, however, all endolaryngeal methods in the most skilled hand available had failed or the size or vascularity of the tumour made intralaryngeal measures impracticable external methods were called for. Tracheotomy might be practised in children with papillomata who might not be amenable to endolaryngeal treatment, more especially if breathing were obstructed, in the hope that spontaneous disappearance of the growth might take place. Tracheotomy was also useful for the removal of a growth so low in the larynx as to be beyond the reach of intralaryngeal instruments.

Professor ROSENBERG in his introductory paper briefly referred to the rare cases in which before the invention of the laryngoscope laryngeal tumours had been removed through the mouth, also to the instances in which a polypus had been spontaneously expelled by coughing, and to the occasional spontaneous disappearance of papillomata following an exanthematous disease. On the other hand, he had never observed spontaneous cure of a laryngeal growth, as had Lennox Browne and others, after the removal of a nasal obstruction. He had noticed no special benefit from inhalations, insufflations, and injections. At the same time in inflammatory nodules, as also in cases of the so-called singers' nodules, he considered that something might be said for astringent treatment, but it remained an open question how far recovery was due to the simultaneous sparing of the voice. On the whole, however, the only right treatment for endolaryngeal tumours, he said, was operation and all laryngologists were agreed that with benign tumours the endolaryngeal method must in the first place, and almost always, be adopted. When dyspnœa threatened, or there was good reason to fear that the endolaryngeal interference would produce so much swelling of the mucous membrane as to cause serious dyspnœa, or when an operation *per vias naturales* might not have the desired result an external operation at the very outset was necessary. If tracheotomy were not imperatively required treatment should always be carried out by the natural passages. The introduction of cocaine into laryngology was a great advance, because by the use of this anæsthetic it was possible to remove a laryngeal tumour without much inconvenience to the patient. On the other hand, against this advantage there was the drawback that the vocal cord to which the polypus was attached became lax and did not become tightened by reflex stimulation and so might be torn away to a certain extent, with the new growth by the less experienced hand. General anæsthesia in adults was only necessary in the very exceptional cases of extreme reflex irritability or nervousness. In children general anæsthesia was often necessary. In the course of more than 20 years' practice he had only once been obliged to use general anæsthesia in an adult. The anæsthesia should not be deep, otherwise the patient, who was in the sitting posture, became limp and would not be maintained in a suitable position and, further, the copious secretion of saliva covered the mirror and if a severe hæmorrhage occurred the blood would be inspired. It was necessary also to cocainise the larynx, as in the slighter degree of anæsthesia the reflexes were not completely abolished. Professor Rosenberg referred to the special difficulty in treating papilloma in children owing to their refusal to permit the use of the laryngoscope, and in referring to intubation he pointed out the possible risk of dissemination of the growth. With regard to endolaryngeal instruments he expressed a preference for the cutting curette and exhibited one which he had had constructed. It was made on the Landgraf principle but its blade had a straight shank, so that when it was applied to the edge of the vocal cord all that was above it could be removed with one cut cleanly and evenly. With this instrument he had removed entire singer's nodules and broad flat tumours projecting only a little beyond the edge of the vocal cord on which forceps slipped easily. Professor Rosenberg mentioned the use of snares for the removal of papillomata. They were especially useful when a large tumour with a relatively thin pedicle had to be removed. With a view of combining the character of the snare with the usefulness of a cutting instrument he had designed a laryngeal snare on the principle of Jaenicke's snare. It was possible with this snare after it was drawn together, by *simply pushing forward the slide to push the snare* out again to catch the tumour in it and to cut it off clean. The snare receded into a *sharp edged slip* in the front part of the snare shaft in such way that the tumour was retained within the snare. He then briefly discussed the treatment of amyloid, lipomatous myxomatous, and adenomatous growths of tumours of thyroid origin and of angeiomata. He considered that the treatment of cavernous angeioma of the larynx *per vias naturales* should not be attempted. He had observed one such broad based tumour which bled freely when touched gently so that he gave up the idea of treating it even with the galvano cautery.

In the general discussion which followed

Dr ADOLPH BRONNER (Bradford) inquired whether formalin had been found successful in the treatment of papillomata.

Dr N C HARING (Manchester) referred to laryngeal growths secondary to, or associated with nasal lesions. The combination of adrenalin with cocaine he had found useful as a local anæsthetic in the removal of growths from the cords.

Dr GREVILLE MACDONALD (London) had not observed spontaneous disappearance of papillomata, recurrence had followed the subsidence of small growths. He had been struck with the rapidity of recurrence during the removal of papillomata the rate of growth appearing to be in excess of that prior to commencing their removal. Operative treatment he considered should be placed before the use of caustics. Thyrotomy had the disadvantage of a tendency to *be followed by impairment of the voice whereas no harm re*sulted from the use of forceps. He was opposed to any external operation for the removal of papillomata in children. The use of snares was attended with the risk of the growth dropping in the trachea.

Dr P WATSON WILLIAMS (Bristol) regarded "singers nodules as inflammatory in origin, and rest of the voice *per se* as the most potent remedy.

Dr STCLAIR THOMSON (London) was opposed to the use of snares and in favour of MacKenzie's forceps for the removal of growths.

Dr PRICE BROWN (Toronto) had found adenoids to be present in all children with papillomata in the larynx. He regarded climate as a determining factor, the papillomata subsiding in a dry climate.

Dr B H SCANES SPICER (London) Dr HERBERT TILLEY *(London)* Mr E B WAGGETT *(London)* and Mr H B ROBINSON (London) also took part in the discussion.

The PRESIDENT (Mr CHARTERS J SYMONDS London) summed up the discussion and observed that all were agreed upon the usefulness of endolaryngeal operations.

Dr DUNDAS GRANT replied.

Dr ALBERT A GRAY (Glasgow) gave a

Demonstration of Macroscopic and Microscopic Preparations of the Human Membranous Labyrinth prepared by a New Method.

The microscopic *preparations* included *sections of the human* cochlea and of that of the guinea pig, the mole, and the white mouse.

Dr BRONNER read a paper on

The Treatment of Non suppurative Catarrh of the Middle Ear by the Local Application of Remedies with Nebuliser and Compressed Air Apparatus.

Dr Bronner considered that the use of Politzer's bag was often harmful and that the proper way to use the catheter was not to blow into it with a Politzer's bag but to use Lucae's double bag. With this a continuous current of air could be kept up and the pressure regulated, better still was the large compressed air apparatus as used in America. By this method the immediate result obtained was not only greater *than after the use of Politzer's bag but more* permanent and the diseased mucous membrane of the Eustachian tube was treated at the same time.

Dr THOMAS BARR (Glasgow) was in favour of Politzerisation when done efficiently as seen by inspection. Auscultation was not quite trustworthy as a test.

Dr L HEMINGTON PEGLER (London) considered that Dr Bronner's apparatus replaced the bougie.

Dr SCANES SPICER inquired whether it was correct that the drum had been ruptured with this compressed air apparatus.

Dr DONNELLAN (Philadelphia) and Mr GEORGE JACKSON (Plymouth) also took part in the discussion.

Dr WILLIAM MILLIGAN (Manchester) read a paper upon

Meniere's Disease and its Operative Treatment.

Mr L A LAWRENCE (London) gave

Notes on a Case of Mastoid Abscess Five Weeks after Measles, Operation Immediate Recovery.

The case was brought forward on account of the following interesting points. The abscess developed in a girl aged five years in little more than a fortnight. As far as it was possible to ascertain no previous disease of the ear had existed. There was never any complaint of pain, notwithstanding that this was the first time the child had had suppurative middle ear disease. There was no pain complained of on palpation over the mastoid. There was only *very slight raising of the temperature. No granulations* were present in the ear and careful examination in the cavity of the mastoid did not reveal any. The treatment adopted was Wilde's own method it was not proposed with any other idea than that of letting out pus, certainly not with any belief that the cure which followed would have resulted from such a simple proceeding, the case being well within a fortnight.

Dr W S SYME (Glasgow) communicated

A Case of Congenital Word Deafness.

The patient was a boy aged nine years fully grown, healthy, and cheerful. The history was that he had never spoken and that he did not appear to understand when he was spoken to and yet he was not deaf because he heard music and was frequently observed to hum tunes which he had heard played and to hear at once when, for instance, a street organ was in the neighbourhood. Except for the defect referred to there was nothing to suggest lack of average intelligence. On examination the tonsils were found to be enlarged and a mass of adenoids was felt in the nasal cavity. The tympanic membranes were retracted. There were no other signs of previous ear disease nor was there anything in his personal history or in that of his family to suggest intracranial disease. After removal of the tonsils and adenoids his hearing power was not appreciably altered. It was impossible to obtain trustworthy results by examination with a watch or tuning fork. When made to watch the lips of the person speaking he attempted to repeat the sound of the words. If his eyes were covered he still attempted to repeat what was said to him getting usually the number of the syllables but not the words themselves.

FRIDAY JULY 29TH

Dr GREVILLE MACDONALD and Dr SAMUEL WEST (London) opened a discussion on

Intranasal Disease as a Determining Factor in the Production of Laryngeal and Pulmonary Affections.

Dr MACDONALD after referring to the unsatisfactory condition of a subject where the conflict of clinical facts the contradictory opinions deduced by authorities, and the small help afforded by the physiologists precluded the *possibility* of establishing a scientific basis for future investigation, offered a working generalisation which might be a step towards the establishment of a definite law.

The speaker dealt with his own observations and divided his cases into three classes: (1) those pointing to the cure or relief of asthma by removing obstruction to easy breathing, or obstruction causing pressure; (2) those where the treatment of any other sort of abnormality in the nose was similarly successful; and (3) those where the mere cauterisation of the mucous membrane in a healthy nose resulted in relief or cure. These three classes were then discussed *seriatim*. In the first, the most favourable forms of obstruction were, first, anterior hypertrophy of the inferior turbinals; second, septal spurs and deviations; third, adenoids; and lastly, polypus. In the second class were found general œdema of the mucous membrane, especially when associated with excessive sneezing, frequently also with chronic bronchitic asthma. Not infrequently the cure of these cases was effected by the electric cautery. Atrophic rhinitis might also be responsible for asthma and the amelioration of the nasal condition might result in cure of the bronchial symptoms. In the third class were placed the cases in which frequent relief and even cure of asthma resulted from the mere cauterisation of the mucous membrane covering the upper part of the triangular cartilage in perfectly healthy noses. So far the clinical facts of the association of the nose with asthma were obvious enough. But they were further emphasised by the observation that occasionally the removal of polypus sometimes originated for the first time the onset of asthma. Passing to his generalisation, Dr. MacDonald invited attention to three points of collateral evidence (1) that whenever a patient complained of frequent and severe cold-taking and any abnormalities whatever were found in the nose, they could almost promise to cure the cold-taking by curing the nasal abnormality; (2) that whenever a patient complained of paroxysmal sneezing, whether of daily attack or of longerinterval, they were tolerably sure of curing him by correcting the nasal disease or malformation; and (3) that a patient with polypus, less often with other form of obstruction, sometimes took cold, often severely, in the form of rhinitis, laryngitis, or bronchitis, after the removal of the obstruction. Probably the sudden exposure of a protected mucous membrane to cold air accounted for each of these accidents as well as the asthma. Remembering these three points, which would be conceded by many observers, Dr. MacDonald said that this generalisation might be formulated. Any treatment that allayed the irritability of the membrane—whether by operation and the ventilating of abnormally protected areas of mucous membrane, or by hardening the hyperæsthetic areas with the electric cautery, or by the exhibition of such local remedies as cocaine, —might modify or arrest the onset of catarrhal attacks, whether they manifested themselves in symptoms of sneezing, laryngitis, bronchitis, or asthma.

Dr. WEST, in introducing the subject, said the affections of the nose which were associated with respiratory difficulties fell into three groups: (1) *obstructive*, where there was mechanical interference with the free passage of air through the nose; (2) *infective*, where inflammatory or infective processes were set up in the respiratory organs by infection from the nose; and (3) *irritative*, where the respiratory condition was of reflex origin excited by irritation within the nose. Speaking of the obstructive group he said that mechanical obstruction in the nasal passages did not of itself cause any respiratory affection unless it were associated, as occasionally happened in children, with adenoids and enlarged tonsils, then deformities might be produced in the thorax such as pigeon breast or Harrison's furrow. What nasal obstruction must of necessity cause was mouth breathing; the air was then not warmed and filtered as it would be in the nasal passages, so that the mouth and pharynx became dry and irritable and chronic pharyngitis was almost the inevitable result. Besides this the parts were prepared for infection. Regarding the infective group, when the mouth and pharynx were moist and when the mouth and tongue were continually washed with saliva, the germs which gained access in the air inspired were got rid of, or at any rate were not likely to grow. But when the breathing was through the mouth the coating which formed upon the tongue, though chiefly made up of dried secretion and cells, teemed with germs of all kinds. If among these there were pathogenic organisms —e.g., the pneumococcus—very serious infection of the air passages and lungs might follow. Thus mouth breathing greatly increased the risk of infection of the air passages. If this danger were more often thought of in the specific fevers, especially of childhood, the frequency of pneumonia and bronchitis, he believed, would be greatly reduced. When there was actually any infective condition in the nose infection, he said, was very likely to spread directly to the neighbouring parts. Nasal diphtheria presented the most obvious and striking example. But so gross an infection as diphtheria was not required to illustrate this fact. Nothing was more common than for simple catarrh to commence in the nose and extend to the pharynx and even to the respiratory organs. Such was the history commonly given by patients of their chest colds. They described the sequence of events graphically and said that their colds always began the same way, starting in the nose, and then spreading to the chest. What was more, these catarrhs might be stopped by antiseptic washes to the mouth and pharynx so that the line of extension was cut, or better still, of course, by the removal of the source of infection from the nasal cavity. Passing to the irritative or reflex group Dr. West said it was by far the most interesting in relation to the respiratory neuroses. Cough, often paroxysmal in character, was common with affections of the nose as it was with those of the throat. Another affection which naturally suggested itself was paroxysmal sneezing. Besides these there were various subjective sensations to which nasal affections gave rise—e.g., sensations of tightness in the chest or shortness of breath or even dyspnœa. All these conditions might stand in some relation to asthma but they were not of themselves asthma, or even necessarily asthmatic phenomena, as they had been called. Of the relation in which asthma stood to intranasal disease much, he said, had been written of late years. Opinions varied widely as well as figures. It was a matter of surprise to those who knew that true asthma was not a common disease that authors should speak of having seen 300, 400, or 500 cases of asthma in a few years. One wondered where they got them from. There were over 5,000,000 of people in London and yet he doubted if there could be got together at the present time from all sides 500 separate cases of spasmodic or true asthma. The term "asthma" must be used then, he said, by these writers in a very wide and comprehensive sense and the numbers could only be made up by including not only all the asthmatic phenomena above referred to but many other phenomena of still more doubtful nature. Accepting, however, for the purpose of discussion the figures given, they might consider, he said, how far they proved the frequency of the association. The problem might be attacked in two ways. 1. A number of cases of asthma might be taken and the frequency of nasal disease among them be determined. Thus Lublinski found in 500 cases 143 with some pathological condition in the nose, that was in 28 per cent.; of the 143, 27 were cured (20 per cent.) and 13 relieved (10 per cent.), or 30 per cent. in all. Francis in 402 cases found nasal disease in 56, that was in 13·9 per cent., and very few of them were relieved by treatment. To make such statistics of real value it was necessary to know the frequency with which these nasal conditions occurred among healthy people, for it was obvious that the association might be accidental. 2. A number of cases of nasal disease might be taken and the frequency of asthma among them be determined. Thus asthma was associated with nasal polypi in nine out of 300 cases (Bäcker), in seven out of 200 cases (Hering), that is in 3·2 per cent. Schmiegelow's percentages were higher—51 out of 239 cases of nasal polypi and 40 out of 502 of chronic rhinitis. Francis in a recent paper maintained that when asthma was associated with nasal lesions the prospects of relief by treatment were less promising than when there was not gross disease. All these statistics were unsatisfactory because of the indefinite meaning attached to the term "asthma," yet they were sufficient to establish a connexion. At any rate, sufficient cases were recorded, and some few Dr. West said he had seen in his own experience in which true asthma associated with nasal disease had been cured or greatly relieved by removal or treatment of that disease. A few cases were also recorded in which asthma had actually been produced in persons not previously known to be asthmatic by intranasal treatment. They might conclude, therefore, that there was a relation between asthma and intranasal disease, but that its frequency was by no means so large as the published statistics seemed to show. Dr. West added that he did not believe any person who was not already asthmatic could be made asthmatic in that way, any more than he could be made epileptic by similar means. As regards the results of treatment he expressed his general agreement with the experience of Sir Felix Semon that though relief might be given in a few cases the prospects of cure were small Asthma, he said, was a respiratory neurosis and closely resembled epilepsy Given the asthmatic or epileptic predisposition in either case the attack might be excited by stimuli from various parts of the body It was therefore the rule to search for a source of irritation and when found to remove or treat it So in asthma when nasal disease existed it was fair to try the effect of treatment Relief might be given, though cure was unlikely, the relief of asthma by remedies applied to a healthy nose might be compared with the checking of an epileptic fit by tying a garter tightly round the leg below the knee Asthma being a neurosis, the effect of mental impression in estimating the result of treatment must be allowed for In conclusion, he said that knowing only too well how difficult the treatment of asthma often was he should be only too glad to treat any possible source of irritation he might discover in the nose or elsewhere in the hope that he might be fortunate enough to give relief

In the general discussion which followed

Mr A J BRADY (Sydney, N S W), whilst holding no strong views on the subject of the treatment of asthma said he preferred to take a middle course between the two openers and referred to cases where benefit had been afforded by nasal operation

Mr COLIN CAMPBELL (Southport) referred to what he called the non obvious cases of nasal disease associated with asthma—namely, those cases which presented no nasal lesion between the attacks but in which during the attack swelling of the nasal mucosa with obstruction was present He had used radium in place of the galvano cautery, and spoke favourably of intratracheal injections for the treatment of asthma

Dr J WALKER DOWNIE (Glasgow) held that polypi were a more common cause than had been stated If the asthma were not relieved by their removal then the latter had been incomplete and some polypi had been left behind and probably high up in the crevices of the nose

Dr STCLAIR THOMSON considered that cases of asthma were not so common as had been stated The patients were often only mouth breathers by night and suggestion played a very large part in the matter

Dr H ALEXANDER FRANCIS (London) had found that the majority of asthmatics had normal noses and that the polypus factor had been overstated The relationship between asthma and the nose he did not regard as that of a nasal disease but as an "inhibition of exchanges "

Dr WATSON WILLIAMS regarded asthma as a neurosis and never relied on any intranasal treatment alone to cure a patient He had found the faradic current to be of service

Dr PEGLER questioned the correctness of the diagnosis of asthma in many cases

Dr SCANES SPICER admitted that when he used the term "asthma " he was at a loss to know precisely what it meant He considered that the physicians should define the term "asthma," "bronchitic asthma," and similar terms which they had introduced He could not lay claim to have cured a case of real asthma

Dr MACRAY MACDONALD (London) cited a case of true asthma in which the patient had a large perforation of the triangular cartilage of the nasal septum

Dr HARING, Dr PRICE BROWN, Dr H TILLEY Dr H SMURTHWAITE (Newcastle) Dr NEWCOMB (New York), Dr DONNELLAN, and Dr DOBSON HORNE (London) also took part in the discussion

The PRESIDENT congratulated the section upon the selection of the subject for discussion as justified by the interesting remarks it had brought out and Dr GREVILLE MACDONALD replied

Dr EUGENE S YONGE (Manchester) demonstrated his model of Meyer's apparatus for Laryngeal Demonstrations He also read a paper on

Some Observations on the Mode of Origin of Nasal Polypi

The paper was largely illustrated with diagrams and drawings of microscopic preparations to demonstrate the results of Dr Yonge's investigation into the pathogenesis of the disease

Dr WALKER DOWNIE contributed a paper entitled Two and a half years' Experience of the Subcutaneous Injection of Hard Paraffin for the Removal of Deformities of the Nose "

Dr PEGLER made a communication on "Benign Neoplasms of the Septum Nasi with particular reference to Bleeding Polypi " The paper was based upon a series of cases of bleeding polypus which had from time to time been brought before the Laryngological Society of London and was illustrated with drawings of the sections

DERMATOLOGY

WEDNESDAY, JULY 27TH

Dr T COLCOTT FOX (London) presided over the section and welcomed the guests

Dr A DOUGLAS HEATH (Birmingham) read a paper on

Acne Keloid

and demonstrated a case The patient had a large red raised surface on the left side of the face and neck the ear being greatly swollen Dr Heath said that there had certainly been some staphylococcic infection The patch had been treated by the x rays

The PRESIDENT considered that the case was difficult to diagnose but it certainly differed from the ordinary type of acne keloid

Dr H G BROOKE (Manchester) had had a case of acne keloid which after treatment with the x rays resembled in many respects the case shown

Dr GILCHRIST (Philadelphia) mentioned that the disease was very common in negroes

Mr J M H MACLEOD (London) thought that the granuloma shown in the sections was very like lupus and that it was not sufficiently recognised that granulomata of this kind could be produced by the staphylococcus aureus and also by other micro organisms

Dr W T FREEMAN (Reading) demonstrated a case of

Leucokeratosis Buccalis

The patient was a young man with dry and sore lips and on the inside of the lips and cheeks were numerous small white patches There was a history of excessive smoking but this had ceased

Dr GILCHRIST expressed the opinion that in many of these cases sebaceous glands would be found in the mucous membrane and these patches were the result of disease of these glands

Dr FREEMAN also demonstrated a case of

Epidermolysis Bullosa

The bullæ had appeared ever since birth and some were present on the elbows One toe nail was wanting

Dr H RADCLIFFE CROCKER (London) mentioned that he had a patient in University College Hospital suffering from this disease in whom the mucous membranes of the conjunctiva and larynx were also affected

Mr G PERNET (London) said that he had recently shown a case in which the conjunctiva was detached from the tissue underneath

Dr GILCHRIST said that it had recently been shown that the deepest layer of the epidermis was very unstable in this affection

Dr LESLIE PHILLIPS (Birmingham) inquired as to the prognosis in these cases A patient under his care, though suffering severely as a child, had become perfectly healthy on attaining adult life

Mr MALCOLM MORRIS (London) opened a discussion on

Pruritus Ani

He pointed out that pruritus ani might be a symptom or an essential disease As a symptom it might depend on general or on local causes It might be due to gout not infrequently alternating with acute attacks in the toe Certain articles of diet such as shell fish and strawberries, might give rise to it and tobacco might have a like effect Rheumatism albuminuria and diabetes might also give rise to it Of the local causes the most frequent were piles, constipation fissure fistula, ulceration, foreign bodies worms pediculi growths and irritating discharges Cutaneous diseases of the region might also cause pruritus It should not however be forgotten that pruritus ani might be a reflex symptom dependent on disease of the genito urinary system or on pregnancy or gall stones As an essential disease there was not much to be said It was a sensory neurosis often originating in emotional disturbances of a depressing character Bronson thought that itching was predisposed to by hyperæsthesia The disease might occur at any age but the cause would vary with the age. In children intestinal worms would be the cause; in young men, local congestion from much sitting, balanitis, and other affections of the genital organs; in young women, menstruation or leucorrhœa; in middle age, piles, constipation, or prostatic disease; in women at the climacteric, one of the many disorders of the menopause; and in old age, venous stagnation, the pressure of growths, or the irritation of ulcers. The scratching might give rise to many secondary conditions and the itching might cause much loss of sleep and mental disturbance. The itching was especially severe at night. Though both sexes were attacked men were more often affected. Mr. Morris considered that most cases were due to the irritation caused by decomposed sweat or to excessive sebaceous secretion. As to treatment, the disease was often refractory but few cases were incurable. Any obvious disorder of the body must be appropriately treated and any local morbid condition found, such as piles, must be removed. The bowels must be regulated, a bland diet ordered, and highly seasoned food must be forbidden. Abstinence from alcohol must be insisted on and coffee must be denied. Calomel, ichthyol, and salol were all useful as intestinal antiseptics. Aloes was contra-indicated. Tonics might be needed. Sedatives and narcotics should rarely be given and opium was especially unsuitable as it had a tendency to cause itching. Large quantities of weak alkaline waters were often a potent aid to local treatment. When all other treatment had failed a course at Harrogate, Strathpeffer, Bath, or Marienbad often proved successful. Locally the most scrupulous cleanliness must be enjoined. The anus must be washed regularly night and morning. Bathing the part with very hot water was of much use and oatmeal, bran, borax, or carbonate of soda might with advantage be added to the water. In some cases very cold water gave more relief. If there was profuse perspiration a weak antiseptic lotion was useful. Of local anodynes cocaine was the most useful, as a suppository, or as an ointment, or as a lotion, but care must be taken not to let the patient acquire the cocaine habit. Menthol was also useful. Strong solutions of bicarbonate or bisulphate of soda were of value. Carbolic acid and tar preparations suited some cases. Balsam of Peru, chloral hydrate, benzoin, and tincture of iodine were of great value. Mercury salts were useful as antiseptics, such as ammoniated mercury and calomel. Nitrate of silver was sometimes effective when applied as a caustic or the actual cautery might be used. Stretching the sphincter might be needed if it was unusually tense and the wearing of a bone plug might be of value. The patient should be kept cool in bed and sleep between linen sheets. Static electricity and high-frequency currents had proved useful in certain cases. There was a distinct risk of over-treatment but the right remedy could be found only by trying all things and holding fast to the good. Perseverance was necessary on the part of the medical attendant as well as the patient. In the purely neurotic forms of pruritus the less local treatment was used the better. Arousing the sufferer to a sense of his duties and responsibilities would often do more than any kind of medicament. Much tact and not a little firmness would be needed in dealing with these patients who had generally no self-control. Hypnotic suggestion had occasionally been successful.

The President, Dr. Radcliffe Crocker, Dr. Eliza L. W. Dunbar (Bristol), Dr. Freeman, Dr. M. B. Hartzell (Philadelphia), Dr. J. A. Brookhouse (Nottingham), Dr. Norman Walker (Edinburgh), Mr. Pernet, Dr. A. J. Harrison (Bristol), and Dr. Gilchrist joined in the discussion.

Dr. Hartzell read a paper on

Benign Cystic Epithelioma of the Type Tricho-epithelioma (Jarisch) and its Relation to so-called Adenoma of the Sweat Glands.

The case on which the paper was based was that of a girl, 14 years of age, and the growths were shown by the sections to have started definitely from the epithelial lining of the hair follicles. Dr. Hartzell maintained that all the cases descirbed under a variety of names, such as syringo-cyst-adenoma, acanthoma adenoides, and syringo-cystoma, were examples of one condition, though differing in certain points.

Dr. Brooke, while agreeing that all these cases belonged to the same series, maintained that in most instances the epithelial growth arose from the ordinary basal epithelium of the skin. He thought that the growths were really a form of nævus.

Dr. Gilchrist thought that from the photographs in this case the growths arose from the hair follicles.

Mr. Pernet read a paper on

The Bacillus Pyocyaneus and Pemphigus Vegetans.

He described a case of pemphigus vegetans in which he had found the bacillus pyocyaneus in pure culture. The man worked in sewers. Mr. Pernet pointed out the possibility of man becoming infected by bacillus pyocyaneus from sewage and thus developing cutaneous manifestations clinically like pemphigus vegetans.

Thursday, July 28th.

Dr. Brooke showed some sections of his cases of Epithelioma Adenoides Cysticum as bearing on the paper read on Wednesday by Dr. Hartzell.

Dr. V. H. Rutherford (London) showed a well-marked case of

Urticaria Pigmentosa

in a boy, aged 17 years. It was of four years' duration and was distributed as pigmented nodules and macules on the extremities and trunk, only the face, the palms, and the soles being free. Each lesion was of about the size of a split pea. The buccal mucous membrane presented symmetrical white patches. Itching was entirely absent and there was no history of wheals or bullæ, but factitious urticaria was readily developed. Sections of nodules presented (1) an increase of the ordinary pigment in the palisade cells of the epidermis, and (2) an infiltration of mast cells in the papillæ and upper layers of the corium.

The case was discussed by Dr. Fox, Dr. Brooke, Dr. Gilchrist, and Dr. Crocker, and it was considered to be a good example of the rare commencement of the disease so late as the fourteenth year.

Dr. J. H. Sequeira (London) opened a discussion on

The Comparative Value of the Old and New Methods of Treatment of Lupus Vulgaris and certain other Skin Diseases.

Dr. Sequeira commenced by saying that the very fact that a debate on the comparative value of phototherapy and radiotherapy and the older methods of treatment had been approved was in itself an indication that the exact position of these measures had not yet been authoritatively determined. The settlement of the question would be materially advanced by the meeting. The greater part of the paper was necessarily devoted to the treatment of lupus vulgaris. The only possible cure of the disease lay in the sterilisation or the complete removal of the affected tissue, not only the visible lupoid lesions but also the surrounding zone already invaded by the specific organism, though not yet showing definite disease. When the face was affected cosmetic considerations should have weight, and if there were two equally efficient measures that which caused the less disfigurement should be preferred. When the disease was situated on the trunk or limbs cosmetic considerations were of minor importance. Excision was the most rational method but it was only applicable to early lupus. In most cases when first seen by the dermatologist excision was usually out of the question because of the deformity which would result. Even skin grafting was not altogether satisfactory from the cosmetic point of view, as the graft was usually of a different colour from the surrounding skin. The want of success in excision was often due to the fear of removing too much, the surgeon naturally trying to limit the amount of disfigurement. Lang himself recorded only 48 per cent. of cases without recurrence. Scraping was usually most unsatisfactory. It removed the visible nodules but as a rule the infected zone beyond them was untouched. The opening up of lymphatic spaces, the natural channel of tuberculous infection, and the want of care in sterilising the instruments between the removal of nodules were undoubtedly a cause of spread of the disease when the operation was carelessly done. Scraping should only be used for the removal of granulations and it should always be followed by caustics or the cautery. It should never be employed at the margin of a patch. Caustics and the actual cautery were too uncertain and led to excessive scarring if used sufficiently to destroy the deep nodules, but they might be used on the mucous membranes as an adjunct to other treatment. Pyrogallol and potassium permanganate were valuable for reducing warty masses and fungating granulations. Scarification gave good scars but it was tedious and inapplicable to deep lupus. The Finsen light treatment with certain limitations was the best treatment for lupus of the skin. The tissues were sterilised with the minimum amount of disfigurement. It was of very great importance to treat thoroughly the margin of a lupus patch and by the Finsen method this was done without any scarring As a result of the care bestowed on the margin of a patch recurrences outside the lupus area treated by the Finsen light were very rare The light must be sufficiently strong to penetrate to the deep nodules and the only forms of apparatus which could effect this were the Finsen and the Finsen Reyn lamps The Lortet and other lamps would cure superficial lupus but even with long sittings the deep nodules in some cases could not be reached The Finsen treatment required constant skilled attention and this was the cause of its expense The preliminary injection of erythrosin as suggested by Dreyer caused severe and very painful reactions and it remained to be seen how far this sensitising of the tissues was likely to prove satisfactory Untouched cases of lupus did best with the light treatment, for where there were much pigmentation and scar tissue cases often proved refractory The main difficulty was the concurrent affection of the mucous membranes for these could rarely be reached by the light and required other treatment Ulcerated surfaces should be prepared for the application of the Finsen treatment and warty masses should be removed by *pyrogallol or other caustics In a few extensive cases* the treatment had had to be abandoned Statistics of the results of the treatment at the London Hospital were given which showed that during the last four and a half years 216 patients had been discharged well and remained well up to date Of eight cases discharged well no recent information had been obtained Three had died from phthisis or miliary tubercle, in 11 cases the light treatment was abandoned as useless, and in 45 cases the patients left for treatment elsewhere or on account of illness The x ray treatment was of the greatest value in the treatment of lupus vulgaris The rays healed up ulcerated surfaces but rarely completely cured, as nodules were usually found in the scar tissue The scar was not always satisfactory for it frequently had telangiectases and there was a decided risk of epithelioma if the treatment was pushed for a long time The x rays were particularly of service in those cases in which the Finsen treatment was inapplicable especially for ulcerated surfaces and when the mucous membranes were affected In the latter cases however relapses were very common For lupus of the skin the results were not in any way comparable with those of the Finsen treatment Radium had been found to remove *nodules but in the small quantity in which it was at present* available it had but a limited field of usefulness High frequency currents stimulated the ulcerated surfaces to heal but did not remove the lupus nodules As to the choice of measures Dr Sequeira considered that for moderate cases of lupus of the skin of the face the Finsen treatment was best preceded by the x rays if ulceration was present or by pyrogallol or permanganate of potassium if the surface was warty or fungating In lupus of mucous membranes the x rays should be used, preceded if fungations were present by the cautery For dry areas of lupus on the trunk or limbs excision was best with, if necessary, skin grafting but if ulceration was present the x rays might be used For widely disseminated lupus probably the best results would be obtained by the tuberculin treatment as recently demonstrated by Professor Wright For lupus erythematosus local measures such as excision scraping scarification caustics the x rays and the Finsen treatment all sometimes removed the lesions, but recurrence was the rule The cause, which was probably a general one was not removed and a cure could not be expected by local measures High frequency treatment was followed by improvement in a few cases but was untrustworthy For the treatment of rodent ulcer the choice lay between excision *x ray treatment and the application of radium* Excision had a limited field of usefulness and could not be recommended unless it could be carried wide of the growth The fact that the disease was so common in the neighbourhood of the eyelids and nose rendered complete excision impossible in many cases The results of the x ray treatment were on the whole, very satisfactory Where the edge was raised [illegible] to the level of the skin [illegible] st rapid results If the [illegible] d be enucleated and the contents of the orbit removed and the x rays applied to the cavity Of 89 completed cases treated at the London Hospital 30 had had more than one course of treatment that is to say in about 33 per cent there were relapses which as a rule were very easily removed Four cases were found to be intractable, and in two epithelioma developed, a condition which could scarcely be attributed to the x rays, for it was recognised long before the introduction of the x rays that in a small proportion of cases of rodent ulcer epithelioma was liable to supervene In two cases which failed to respond to the x rays radium effected a cure Radium was especially useful in cases of rodent ulcer of the eyelids and in the nose parts to which the x rays could only be applied with great difficulty The x rays had *given very* disappointing results in epithelioma proper Only cases where operation had been refused or was impracticable were treated The local lesion had disappeared but the enlargements of [illegible] more resistant In mycosi[illegible] at present the only mean[illegible]

Dr BROOKE agreed that the Finsen method was the best for unbroken lupus When the mucous membranes were affected high frequency currents had given good results as by passing a vacuum electrode into the nasal cavity The Roentgen rays were very useful and for sycosis they were a powerful therapeutic aid

Dr MACLEOD considered that the telangiectases following *the x rays were very difficult to remove For intra nasal* lupus radium was probably the best In leprosy the nodules were removeable by the x rays

Mr J HALL EDWARDS (Birmingham) had found the x rays most suitable for extensive cases of lupus

Dr S E DORE (London) said that in untreated cases of lupus vulgaris of small extent the Finsen method was the best because it gave the best scars, even if there was much scarring from previous treatment the Finsen treatment was best In cases of extensive but superficial lupus the preliminary treatment with the x rays would reduce the disease so that the isolated nodules might be treated with the Finsen light, or the two methods might be used concurrently If there was extensive disease with dense masses of lupus infiltration preliminary surgical measures such as scraping or excision, were needed before employing the Finsen light or the x rays

Mr PERNET mentioned that he had obtained good results with the Lortet Genoud lamp

Dr GILCHRIST thought that in the treatment of malignant disease the x rays were useless if they had to pass through healthy skin In the treatment of acne vulgaris the x rays were a valuable adjunct

Dr O'BRIAN had found radium of value in treating the nodules of Bazin's disease

Dr HARTZELL had employed with benefit the x rays in psoriasis

[illegible] found diseased foci in [illegible] Scraping alone was un[illegible] wed by the cautery Radical treatment had the great advantage that it saved the patient from the possibility of pulmonary phthisis which not rarely followed neglected lupus For lupus nodules nitric acid applied on a match destroyed the roof and then the yellow oxide of mercury ointment might suffice to cure the nodule

Dr F G GRAHAM LITTLE (London) expressed a high opinion of the value of Professor Wright's inoculations for lupus and in severe sycosis

Dr FOX thought well of the x rays in parasitic conditions such as ringworm

Mr HALL EDWARDS read a paper on

Chronic X ray Dermatitis

illustrated by two cases and in the discussion which followed Dr CROCKER advised the constant application of lactate of lead especially for the acute forms of x ray dermatitis, and Dr NORMAN WALKER emphasised the importance of prevention

FRIDAY JULY 29TH

Dr MARTIN demonstated a case of Kaposi's Sarcoma The patient was 75 years of age and the disease first appeared on the feet and arms as bruise like spots They had gradually spread and microscopically they had the structure observed in cases of this disease

Dr ARTHUR WHITFIELD (London) opened a discussion

On the Relative Importance of the Bacterial and Other Factors in the Causation of Skin Diseases

He commenced by saying that of recent years the very great importance of bacteria in connexion with the production of diseases of the skin had received full recognition and he ventured to suggest, that perhaps an undue importance had been assigned to them. The diseases of the skin which were associated with the presence of organisms might conveniently be divided into four groups. In the first group were put those skin diseases in which the contagiousness was marked and the disease was undoubtedly the effect of the presence of a special organism. As examples of this class, might be quoted ringworm and soft sores. In the second group were put those diseases of which the contagiousness was not marked, but a special organism was present. Inoculation was difficult. An example was pityriasis versicolor. In the third group the contagiousness was certain but the organism was present on normal skin. Impetigo contagiosa would fall into this group. In the fourth group may be placed those skin diseases of doubtful contagiousness; an organism was present which was usually to be found on healthy skins. As examples may be mentioned seborrhœa and acne. With regard to the first group the organism was the essential element in the etiology, and as the contagiousness was marked the suitability of the soil was not very important, but even in this group it could not be disregarded; for instance, in the case of ringworm there were few children who escaped and adults were but little liable to the affection. In the second group the suitability of the soil was of much greater importance, and therefore it was more difficult to inoculate the disease, even though we were quite sure that the organism was the cause of the disease. In the third group the organism was certainly of importance as was shown by the ready inoculability of the disease but there were other conditions which must coöperate. For instance, every one knew that pediculi capitis gave rise to an impetigo contagiosa; it was not merely the scratching, for other forms of irritation of the scalp did not cause impetigo. Dr. Whitfield was inclined to think that the pediculi in some way prepared the skin for the organisms of impetigo contagiosa. Possibly the streptococcus might become modified, for it was known that streptococci could be trained to attack different parts of the body. Staphylococci impetigo was not very infectious and probably a streptococcic infection preceded it. The diseases placed in the fourth class usually occurred in persons suffering from some defect of health, though the presence of the local organism was probably also required. This subject naturally led to the question, What are the normal flora of the skin? Sabouraud says that there are no normal flora—that is to say, that in health organisms did not grow on the skin, though individual microbes might lodge in the irregularities of the surface of the skin. There was much to be said in favour of this view. It should be borne in mind that the secretions of the skin were very suitable culture media for micro-organisms. Therefore if any secretion was excessive the organisms which were merely lying in units on the skin might suddenly develop and form colonies. If a man sweated much the sweat soon became sour because of its having undergone decomposition. In seborrhœa three main organisms have been described: (1) the microbacillus of Sabouraud; (2) the bottle bacillus; and (3) the non-liquifying bacillus. The microbacillus of Sabourand was present on all oily skins; it could be found in acne and in cases of greasy baldness. Dr. Whitfield, bearing in mind the oiliness of the skins of negroes, examined some cases and found this bacillus present in large numbers. It was also present in the comeda. He did not look upon this bacillus as the cause of the excessive secretion, whether this was derived from the sebaceous glands only or from the sweat glands as well. He considered it as very doubtful if the bacillus had anything to do with the fall of the hair, for in women there were many microbacilli but rarely loss of hair. The bottle bacillus was always to be found where the sebaceous glands were well developed. It was found in great abundance in the grouped comedones of infants. Unfortunately it had never been found possible to grow the bottle bacillus. The non-liquifying bacillus was very plentiful. It could be found not only in seborrhœa, but elsewhere, as in the dry pityriasis of the face. Dr. Whitfield had attempted to inoculate it but had not been successful. In seborrhœa eczema there were probably two factors: (1) free secretion and (2) septic organisms; neither could have any effect without the other. Probably another etiological element was a toxin absorbed from the alimentary canal, for faults in metabolism had a marked effect on the irritability of the skin. The paper was illustrated by lantern slides.

Dr. GILCHRIST expressed the opinion that much work on the flora of the skin had been done by surgeons. With regard to the etiology of acne he had found the bacillus acnes 60 times in succession and had been able to grow it in acid glycerine agar. Also he had been able to show that the blood of acne patients caused agglutination of the bacillus acnes, but this did not happen in cases not suffering from acne. This was a very strong proof in favour of the specific action of the bacillus acnes.

Dr. FOX considered that comedones were only an exaggeration of the little plug which was so commonly found in sebaceous glands.

Dr. LESLIE ROBERTS (Liverpool) expressed his surprise that so little stress had been laid on heredity in seborrhœa. He thought it should be borne in mind that seborrhœa was not a secretion but purely an exfoliation.

Dr. EDDOWES said that he had often noticed that those who lost their hair from seborrhœa had previously had a great quantity of hair and he was therefore inclined to think that the first action of the disease was to stimulate the growth of the hair.

Dr. A. DOUGLAS HEATH (Birmingham) thought that symbiosis might explain many of the difficulties.

Dr. DORE asked for information as to the standardisation of culture media, as he could not make some organisms grow which Sabourand said would grow.

Dr. W. K. WILLS (Bristol) drew attention to the action of x rays on acne; the eruption was probably removed by the drying up of the secretion.

Dr. LITTLE mentioned that when the staphylococcic inoculation method of Dr. Wright was employed only the staphylococci were removed and yet the eruption disappeared although the other organisms were left.

Dr. GILCHRIST read a paper on

Erysipeloid

based on 329 cases. The eruption consisted in erythematous blotches on the hands with a well defined red edge. There was often much pain but lymphangitis was rare. There was no tendency to suppuration. The cases appeared at Baltimore in June and disappeared in August. In 323 of the cases the patient had been pinched by a crab or scratched by a piece of the shell at the centre of the patch. The incubation appeared to be about two days on an average. It tended to disappear after a few weeks. He had been unable to find any organism and inoculation experiments had failed. Injections hypodermically of crushed crabs had had no effect. He was inclined to think it was due to a toxin and not to an organism.

Several members stated that they had never seen the disease, but others had seen a few cases.

Dr. ROBERTS read a paper on "Non-parasitic Cutaneous Reactions."

Dr. G. NORMAN MEACHEN (London) read a paper on

The Influence of Peripheral Nerve Irritation upon the Production of Diseases of the Skin.

It was now generally recognised that many cutaneous manifestations were connected with the trophic influences of the nerves of the skin, but it had not been sufficiently acknowledged that local irritation of the peripheral nerves might influence the production of skin diseases. The dental theory of Jaquet provided a very plausible explanation of one variety of alopecia areata, especially as in many cases the extraction of the carious tooth had been speedily followed by a return of the growth of the hair. The ocular nerves might possibly also possess considerable influence upon the progress of alopecia areata. Pernet and Whitfield had both suggested that the loss of growth of the hair might be due to errors of refraction, and cases had been described in which the hair was quickly renewed after the prescription of appropriate glasses. The influence of dental irritation in provoking eczematous outbreaks in infants had long been recognised. Irritation arising from cerebral and spinal nerves might predispose to eruptions of an herpetic type, and Gaucher had related several cases in which herpes appeared after quite superficial injuries. In such cases it was reasonable to suppose that the contusion of minute terminal nerve filaments acted as a source of irritation and so determined the appearance of an eruption. Scratching appeared to give rise to lichen planus and possibly the scratching might act reflexly.

TROPICAL DISEASES

THURSDAY, JULY 28TH

Dr J W W STEPHENS (Liverpool) opened the discussion on

The Prophylaxis of Malaria

He pointed out the necessity of regarding malaria as a contagious disease, the source of contagion being principally the child population carrying malarial parasites in its blood The species of anophelines which conveyed malaria in a greater or less degree were —(*a*) In Europe the anopheles maculipennis, anopheles bifurcatus, P superpictus and M pseudopictus (*b*) In Africa anopheles maculipennis P costalis M funestus and P chaudoyei (*c*) In India M Listoni, M culicifacies and N maculipalpis (?) (*d*) In North America anopheles maculipennis (*e*) West Indies anopheles albipes In all there were about one dozen out of 100 known species It was therefore important before undertaking the extermination of anopheles in any given district with a view of preventing or eradicating malaria to determine the variety of anopheles present otherwise useless expense and labour might be involved Some mosquitoes bred in dirty puddles for instance the M Rossii which was harmless, others preferred clean water and streams such as the M culicifacies which was an active agent in spreading malaria It was therefore useless to sweep out the foul puddles and to leave the running streams uninvestigated The normal flight of anophelines did not exceed some hundreds of yards, therefore in the centre of towns although some kinds of mosquitoes prevailed such as stegomyia anopheletes were only met with in the outskirts where clear running water was ... In India it was proved th

a mile from anopheles

from malaria, in Free

distance was less—about from a quarter to half a mile only The measures usually adopted for the prophylaxis of malaria were the following 1 Anti larval This was the fundamental method of prevention and should in the form of

in certain instances effective 3 Segregation of Europeans On general sanitary grounds this was highly to be recommended the natives being the source of infection to Europeans The objection to this plan was that the native was neglected while he ought to be regarded as worthy of protection as the white man When the native was advanced in sanitary and general education to the same position as the white man this sentimental idea might be listened to but not till then Of the determined attempts to exterminate mosquitoes the operations at Ismailia and Mian Mir (Punjab) were the best known The former was in a limited area, the latter in a large cantonment where irrigation canals were numerous and therefore difficult to deal with but the failure at Mian Mir was due not to the irrigating channels within the area but to immigration from without

Major RONALD ROSS C B (Liverpool), read a communication upon

The Anti Malarial Experiment at Mian Mir (Punjab)

With a view to demonstrate b

of all anti malarial measures

of anopheles larvæ, operations a

In criticising these operations Major Ross dealt with the omissions in the report of dates maps and the number of the population of the cantonment There was an indefinite account of the organisation at work on the experiment but the amount of money expended seemed too small for a large undertaking of the kind to have been thorough The test applied for ascertaining the reduction in the number of mosquitoes present seemed also unsatisfactory Individual experience in regard to these points appeared worthless and only the general consensus of opinion could be approximately relied upon The test for malaria reduction by the examination of the blood of the native children in the neighbourhood was a long one and of a variable quantity The effect of the operations by Captain S P James, I M S and Lieutenant S R Christophers I M S on the number of mosquitoes although extending over one and a half years was inappreciable or even negative The operations at Mian Mir proved little or nothing except that in an area of the extent of the cantonment selected for experiment it was impossible by the expenditure of £200 or £300 to make any impression on the number of mosquitoes within the area or on the amount of malaria present They had still to determine in work of this kind (*a*) the radius of operations required to reduce the density of a given species of mosquito to a given percentage, and (*b*) the percentage of mosquito reduction required in order to obtain ultimately a given percentage of malaria reduction

Captain JAMES and Lieutenant CHRISTOPHERS contributed a paper on

The Success of Mosquito Destruction Operations at Mian Mir (Punjab)

They carried on the work of mosquito destruction and malaria reduction for over two years and the result of the attempt according to their statement was in both cases poor and totally out of proportion to the means employed They did not ascribe the failure to want of thoroughness or to peculiar conditions in Mian Mir but considered that the difference between their efforts and those of others was entirely due to the great disparity in the value of the tests used in estimating the reality of results achieved The Mian Mir experiment proved the difficulty of conducting successfully operations of the kind Local destruction of breeding places was quite futile so long as the infiltration of adult mosquitoes from outside the area operated upon was possible Captain James and Lieutenant Christophers had no hesitation in challenging as absurd the reported successes of mosquito brigades in ridding a town of malaria

Dr ANDREW DUNCAN Lieutenant Colonel I M S (retired) said that in military campaigns in tropical countries it was necessary to pay attention to the race and age of the soldiers to the season of the year for operations to the clothing of the men the period of marching the camping grounds the food and the precautions at night Dr Duncan recommended that flannel should be worn that the food should be sufficient and the diet not a monotonous one and that where possible the soldier should sleep on the ground with merely a blanket for bedding Malarial fever was to be prevented by (1) protection against the infected mosquitoes (2) destruction of the infected mosquitoes and (3) prophylactic drugs Quinine was the best medicinal prophylaxis in doses of three grains every morning

Mr W HENRY W STRACHAN C M G principal medical officer of Lagos West Africa sent

Notes on the Prophylaxis of Malaria

The rule to be observed in malarial areas should be ' Do not permit yourself to be bitten by mosquitoes This involved measures taken for the destruction of mosquitoes but these involved an expenditure of money and time almost entirely out of the range of practical work Mosquito destruction resolved itself into elimination of all areas where the breeding of mosquitoes was possible or probable be it wells swamps puddles around houses tanks flower vases &c To ward off adult mosquitoes mosquito nets mosquito proof rooms punkahs and burning certain materials in rooms should be resorted to Among accessory measures Mr Strachan advocated the prevention of chill avoiding exposure in the sun during the hottest time of the day and temperance in all things Quinine as a prophylactic in daily doses of five or six grains or in larger doses once or twice weekly was attended with marked benefit When quinine could not be taken thiocol promised fairly well as a malarial prophylactic There was much to be said against the segregation method of dealing with malaria but although in theory it was not carried out in practice race associated with race and solved the problem involuntarily At the present time anti mosquito measures and the administration of quinine summed up the prophylaxis of malaria

In the discussion which followed these papers on the prophylaxis of malaria the following took part

Colonel KENNETH MACLEOD I M S (retired) referred to the food of the mosquito larva and considered this an essential point in the matter of malaria prophylaxis The conveyance of mosquitoes by railway carriages and ships was no doubt a possible means of dissemination The use of the broom in sweeping away dust from dark corners where mosquitoes lodged was an important element in prophylaxis Irrigation was so necessary a part in the agriculture of India that to sweep it away would mean famine, other methods, such as improved drainage, would no doubt be found which would render this unnecessary

Dr D E ANDERSON (Paris) remarked that the smoke in the native huts in Madagascar served as an efficient mosquito destroyer; the smoke merely paralysed the mosquito, however, for the time being.

Major G. H. FINK, I.M.S. (retired), stated that there were many points in Dr. Stephen's paper which placed us in a very difficult position as to the prime origin of malaria while considering Ross's investigations with regard to the particular species of anopheles in which he (Ross) had found the malarial parasite. Plehn's "primitive bodies" or karyochromatophile granules, mentioned in Manson's book, had yet to be thoroughly investigated, since it was acknowledged that very little was known about them, except that they are to be seen in the blood of Europeans on the West Coast of Africa soon after their arrival there, but attended with anæmia, and this before malaria had pronounced itself in the individual. It might be considered as a "latent phase" of malarial fever parasites, but an organism on the borderland between the vegetable and the animal, which presented both the male and the female element, which had to pass through the usual cycle before its exact position could be recognised in the body of the mosquito and before malarial fever was transmitted through the bite of that insect to man.

Dr. PHILIP O. MALABRE (Southport) inquired if there was any truth in the assertion that dragon-flies destroyed mosquitoes.

Captain C. E. WILLIAMS, I.M.S., stated that dragon-flies preyed on mosquitoes and where these flies existed in numbers mosquitoes were rare. He had lately raised dragon-flies from the larvæ and fed them on living mosquitoes which they seized when on the wing. Captain Williams had also raised nymphæ of various species of mantis and fed them successfully on mosquitoes.

Mr. F. J. A. BERINGER (Colonial Service Gold Coast) stated that he tried quinine prophylaxis in Hong-Kong amongst the British troops but without marked beneficial results. The cases of fever might have been a little less severe, but there was no diminution in the actual number of cases. The diagnosis of malarial infection was chiefly clinical but in many examined the malarial parasite was found.

Sir PATRICK MANSON, F.R.S., D.Sc., remarked that the failure of quinine to act as a prophylactic amongst troops in Hong-Kong led him to doubt the accuracy of the diagnosis of the kind of fever the soldiers were suffering from. In several countries, and especially some of the Pacific islands, malaria was unknown at present. It would be well to consider whether any means could be devised to ward off malaria from them.

Professor W. J. SIMPSON observed that it was a pity the experiment of mosquito extermination had been tried at Mian Mir. The cantonment did not lend itself to experimental work of the kind except under a properly organised staff, which at Mian Mir was quite insufficient. The recent proposition that the civil surgeons of five municipalities in India should carry out a campaign against mosquitoes was a mistake. The civil surgeons in India have an enormous amount of clinical and practical work without indulging in anti-mosquito crusades, and to ask these overworked medical officers to undertake extra duties of the kind proposed was certain to end in failure. India was without a proper sanitary organisation but for the sake of the people of India it would be soon created.

Dr. ALEXANDER CROMBIE, C.B. (London) remarked that we had recently been given two object lessons—one in Havana, where the work of destroying mosquitoes and eradicating yellow fever had been successful; and the other at Mian Mir, where the results had failed from want of sufficient organisation. So long ago as 1342 in Spain malaria was associated with the irrigation necessary for rice growing and the cultivation was prohibited by law. The work of the civil surgeons in India was enormous and to add mosquito destruction to their duties, considering the enormous tracts of country they presided over as health officers, was sure to be inefficiently performed.

Dr. LOUIS SAMBON and Major T. MCCULLOCH, R.A.M.C., also joined in the discussion.

Dr. F. M. SANDWITH (lecturer at the London School of Tropical Medicine) read a paper on

Infectious Jaundice.

He compared the disease, which was endemic in Smyrna and in Alexandria and epidemic in Nauplia in Greece, with the cases of Weil's disease reported from Germany, England, the United States, and China. He also suggested that the disease probably existed in India and other tropical countries, though masked under other headings. Infectious jaundice was an acute infection characterised by fever, jaundice, enlarged liver and spleen, and nephritis. It occurred chiefly among male adults during the summer months and was a filth disease engendered by contamination with sewage or putrid meat. He suggested mosquitoes or other insects as transmitters and recommended the destruction of all mosquitoes in one of the infected towns as a useful experiment. He gave reasons for not accepting the idea of this disease being yellow fever in a modified form and suggested that the differences between infectious jaundice and Weil's disease could be accounted for by variations in the climate, temperature, race, and sanitary surroundings.

Major H. B. MATHIAS, R.A.M.C., read a paper on

Jaundice in South Africa.

The experience of the disease was gained by Major Mathias during the late South African campaign, when jaundice seemed to have been prevalent amongst the troops, no fewer than 5648 cases being recorded. The period of greatest incidence was during the South African autumn and winter months from February to June. The severity of the disease varied; in some there was little, if any, pyrexia or constitutional disturbance; in others there were nausea, severe pains in the back, initial rigors, a temperature from 100° to 103° F., pain in the epigastrium and right hypochondrium, enlargement of both liver and spleen, and occasionally a pear-shaped tumour over the gall-bladder. The jaundice usually occurred during the third day of the illness and might persist a month or more. The mortality amongst British troops was *nil*, but the attack was followed by great debility and mental depression. Major Mathias concluded that the disease was due to a definite infection of a toxic form and that the poison was generated in consequence of insanitary conditions. That the jaundiced condition was associated with enteric fever would seem confirmed, for it appeared each year when enteric fever had reached its maximum in the autumn and was on its decline. This was in accordance with observations made elsewhere and was a point of great interest, but there was no direct evidence to connect the epidemiology of the two diseases, yet nevertheless it appeared that there was a distinct form of epidemic jaundice following outbreaks of typhoid fever, and clinical experience would point to the former being consequent upon enteric fever and not true Weil's disease.

Colonel MACLEOD remarked that in the island of Lewis some 45 years ago he remembered an epidemic of jaundice associated with pain, vomiting, fever, clay-coloured stools, and dark urine, &c., so that this disease was not confined to any particular country or locality.

Dr. M. A. RUFFER stated that in Alexandria he had witnessed outbreaks of bilious typhoid fever in which the mortality amounted to 20 or 30 per cent. of those attacked. He did not think that these were cases of Weil's disease. In bilious typhoid fever the patient became suddenly extremely ill; not so in Weil's disease. Moreover, no bacterium were found in the blood or tissue of bilious typhoid fever, nor did these infect animals when tested experimentally. Kidney lesions were noted in the Alexandria outbreak corresponding to those met with in yellow fever. Hæmorrhages round the hepatic veins and emboli of hepatic cells within the hepatic veins were met with.

Major ANDREW BUCHANAN, I.M.S., said that at one time there were in 1899 150 cases of epidemic jaundice in hospital at Nagpur. In these cases the temperature was raised for only a day or two, the symptoms were those of ordinary jaundice, and the patients lost weight. Only one of the persons attacked died. Adult natives in India were so seldom attacked by typhoid fever that it did not seem possible to connect the two diseases in this particular instance.

Mr. JAMES CANTLIE (London) described a case of Climatic Bubo in a patient from Mysore who had just landed in England. In Mysore plague was prevalent and the patient was freely exposed to plague infection. After leaving Mysore he called at Madras, Colombo, and Suez, and on the day before landing in England on Feb. 24th found a tender gland in the left groin. By March 4th, the evening temperature had reached 101° F. Febrile conditions continued, pus was found around the gland on March 7th, and the gland was excised. Specimens of the pus and gland tissue were sent to Professor Hewlett who succeeded in cultivating a bacillus resembling the plague bacillus. The cultures proved innocuous to animals. The association between climatic buboes and plague had been frequently referred to by Mr Cantlie and he had applied the name pestis minor to these complaints. A definite bacillus was found by Professor Simpson in Calcutta in cases of the kind and Mr Cantlie was inclined to believe that the cases of plague referred to by Koch as occurring in German East Africa were of the nature of pestis minor and not true plague. It was well known that climatic buboes had been prevalent for some time on the East African coast, and seeing that the centre of plague referred to by Koch had not extended at any known period, the probability of an extension inland from the eastern coast of Africa of the disease climatic bubo (pestis minor) explained the outbreak related by Koch. Lately Mr Cantlie had seen a case of climatic bubo from Northern Nigeria where the disease was described as a new complaint. It would therefore seem that the disease climatic buboes (pestis minor) was travelling across the African continent from east to west.

Dr M. CAMERON BLAIR (Northern Nigeria Protectorate) said that quite 25 per cent of the native soldiers in Northern Nigeria suffered during the year from indolent inguinal buboes which did not generally suppurate. He had always regarded these buboes as venereal in origin.

Mr JAMES CANTLIE read a paper upon

Subcutaneous Nodules attended by Febrile Attacks

in a patient from the Kolar goldfields, Mysore State. The patient had had several eruptions of these subcutaneous nodules. When seen by Mr Cantlie in London there were three nodules noticeable on the outside of the left leg, another on the inside, and a third on the front of the left thigh. The nodules felt like shotty particles beneath the surface, the skin over two of the nodules was slightly red for an area of a quarter of an inch all around the nodules. The patient had had similar lesions on the upper extremities and on the right lower limb, which came suddenly, lasted some three weeks, and disappeared spontaneously. With the appearance of each nodule a slight attack of fever occurred. Mr Cantlie excised one of the nodules and sections of the growth were made by Dr G C Low and exhibited. No parasite was to be seen macroscopically or microscopically, at one point in the nodule a freshly formed inflammatory thickening was evident with widely dilated lymphatic spaces. Mr Cantlie was unaware that a similar condition had ever been described.

FRIDAY, JULY 29TH

Major W B LEISHMAN, R A M C, opened a discussion on the Leishman-Donovan bodies with a paper entitled

The Nature and Significance of the Leishman-Donovan Body

The disease associated with these bodies, Major Leishman remarked, was by no means uncommon in the tropics. The first case in which the "bodies" were found was that of a soldier, invalided from Dum Dum in November, 1900, with tropical cachexia and splenomegaly, and soldiers at Netley presenting a similar clinical picture were so frequently found to have served at or near this station that he termed the condition "Dum-Dum fever." The name was, of course, only a temporary expedient. Since this discovery cases had been reported from three or four widely separated districts of India, from China, Tunis, Algiers, Arabia, and Egypt. The parasites, although originally found in the spleen, had since been met with in the liver, the mesenteric glands, the bone marrow, the kidney, and in ulcers involving the intestinal mucosa. The parasites appeared to be chiefly, if not solely, intracellular, and occurred in the protoplasm of large mononuclear cells, probably "macrophages." *Neither the parasites nor the cells which* harboured them appeared to suffer from their mutual association. In specimens obtained by splenic or hepatic puncture during life the parasites were, however, usually found free in groups of several members embedded in a structureless stroma, which was probably disintegrated remains of large mononuclear cells due to mechanical violence. The signs and symptoms of the physical condition associated with the "bodies" were (1) splenic and hepatic enlargement, (2) an earthy pallor of the skin, (3) a continued irregularly remittent fever; (4) hæmorrhages from the nose, gums, and subcutaneously, (5) œdema *of a transitory nature in the limbs;* (6) congestion of the lungs, diarrhœa, and dysentery had been observed, and (7) a marked mononuclear increase. The symptoms were very similar to those noted in kala azar, and Bentley and Rogers had found the bodies recently in the spleen of persons suffering from this disease. The nature of the parasite had been variously interpreted. (1) Major Ross believed it to be a new genus of sporozoa; (2) Laveran considered the bodies to belong to the piroplasmata and (3) Leishman thought the of a flagellate not actually by Marchand and Ledingham had led to the same conclusion as Leishman. Schaudinn, from observations made on the transformations undergone by a blood parasite of the stone owl when taken into the stomach of a mosquito (culex pipiens), came to the conclusion that this halteridium was, in reality, a sexual form of a true trypanosome to which he gave the name trypanosoma noctuæ. Prowazek supported Schaudinn's conclusions and it would seem that between the resting forms of trypanosomes these authorities described a very close resemblance with the Leishman Donovan bodies was traceable. From the frequency with which dysenteric complications had been reported in the course of the disease and the fact that the "bodies" had been found in ulcer of the intestine, they seemed to have a key to the channel of elimination of the parasite from the human body. The discovery by Wright that similar parasitic bodies were met with in Delhi boils was also of considerable importance. The announcement by Captain Rogers that trypanosomes had developed from cultures of these bodies seemed to clench the association between the bodies and trypanosomes.

Major C DONOVAN, I M S, sent a communication on

Human Piroplasmosis

Major Donovan accepted the view of Laveran and Mesnil that the Leishman Donovan body was a piroplasma. He found the parasite in 72 cases out of 1304 patients admitted into the General Hospital at Madras. The disease associated with the "bodies" attacked the poorer class of natives of Madras of both sexes and of all castes and creeds. Eurasians and Europeans were also subject to the disease. Amongst the signs and symptoms enumerated by Major Donovan he mentioned cancrum oris, œdema of the feet, and ascites. Amongst the causes of death he notified general infection, cancrum oris, œdema of the glottis, diarrhœa, peritonitis, broncho pneumonia, and one case of hæmorrhage from splenic puncture. Examinations of the blood in cases of piroplasma infection showed decrease of red corpuscles, no actual increase of leucocytes, but a relative increase of mononuclears. The urine usually contained albumin and invariably pigment. Four cases of the disease were related in detail by Major Donovan.

Dr CHARLES A BENTLEY (Tezpur, Assam) sent

Some Notes upon Kala azar and the New Bodies

Dr Bentley described kala occurring in many parts countries. Occasionally the form. Amongst the most notable signs and symptoms were gradual enlargement of the spleen and sometimes of the liver, emaciation, irregular fever, pain in the ends of the long bones, gastro intestinal or dysenteric symptoms, secondary anæmia, and occasional hæmorrhage from the stomach, gums, and nose. Of all forms of the disease the dysenteric was the most rapidly fatal. The disease was most resistant to treatment. Quinine was useless and removal to an uninfected site promised best. During an epidemic few might escape and the case mortality might reach 90 per cent. As the epidemic waned the virulence lessened until at last the patient would appear to be suffering from "ordinary malaria." The only accurate method of differential diagnosis was the examination of the blood drawn *from the spleen* during life. Dr Bentley described the parasite and its situation in relation to the blood cells. He considered that it had not at present been definitely shown that the "body" was more than the spore of some micro- or myxo sporidian and it might yet prove to be a phase in the life history of some flagellate or other organism. He had found the parasitic body in dogs, cats, goats, cattle, rats, deer, bats, fish, frogs, and snakes, but not in the stomach of any biting fly or insect, nor in any human skin lesion. An interesting observation by Dr. Bentley carried support to Sambon's contention that certain mud fish on the shores of the Victoria Nyanza had a determining influence in the spread of *trypanosomiasis*. In Assam Dr Bentley found that certain species of mud fish taken from marshes or pools adjacent to kala azar infected lines in nearly every instance showed marked trypanosomiasis and that fish taken from pools at a distance from any possible source of fæcal contamination appeared to be entirely free from trypanosome infection.

Captain LEONARD ROGERS, I.M.S. (*acting professor of* pathology, Calcutta), contributed a paper on

Cachexial Fever in India associated with Cunningham-Leishman-Donovan Bodies.

Captain Rogers said that he believed that the great majority of cases known hitherto as "malarial cachexia" occurring in Calcutta at any rate during the hot weather months, when true malarial cases were at their minimum, were really cachexial fever due to the new parasite. The most interesting part of Captain Rogers's paper referred to the cultivation of the protozoal parasite of cachexial fevers. In experimenting in this direction Captain Rogers added the blood obtained from splenic punctures of persons suffering from the disease to a small quantity of sterile citrate of soda solution to prevent the blood clotting and then kept it under different conditions. When the solutions were kept at blood heat the parasites very rapidly degenerated and disappeared; yet when placed in a cold incubator at 27° C. they retained their natural conditions for several days and stained perfectly. They also increased in numbers, so that instead of two cultures in a field of an oil immersion lens as in the freshly taken blood, after a day or two scores and even a hundred of very young forms could be found in the same area. Numerous divided forms were also found in even a single field, so that there was clear evidence of the survival and multiplication of the organism outside the body. When the temperature of the incubator was reduced to 22° C. the parasites were seen to multiply more readily, as many of the forms seemed considerably larger and appeared in a single day. Captain Rogers looked for flagellated bodies and found in two cultures unmistakable trypanosomes, together with smaller pear-shaped flagellated bodies and other intermediate forms. The more marked cases showed completely developed trypanosomes with thick flagella and macro- and micro-nucleus after incubation for one day, while the living forms were also seen in the blood culture moving rapidly among the corpuscles. It is worthy of note in regard to the possible method of spread of the disease that in October, 1901, Surgeon Chatterji found a trypanosome in the proboscis of a mosquito.

Tropical Splenomegaly and Oriental Sore

was the title of a paper by Lieutenant S. R. CHRISTOPHERS, I.M.S. The nature of the Leishman-Donovan bodies, according to Lieutenant Christophers, was as yet undetermined, but that they were affiliated with some flagellated organism would seem likely. He pointed out some time ago that the matrix of the zooglea mass was merely the cytoplasm of endothelial cells of the spleen, more especially that derived from the large macrophages. The "bodies" did not appear to be a parasite of the red blood cell and they would appear to be no more a blood parasite than were the organisms of septicæmia or the tubercle bacillus. Recently Wright in America discovered the "bodies" in the granulation tissue of tropical ulcer. In India Captain James also found them in oriental sore. Lieutenant Christophers found the "bodies" free in blood from the spleen and believed them to have been liberated artificially by rupture of cells, more especially the large macrophages. The same held good in the case of the liver and bone marrow and the condition might be described as an engorgement of the endothelial cells with the parasite. In the lung, testis, and kidney the "bodies" were seen lying in cells of an endothelial nature and closer investigation showed them in the endothelial cells of the finest capillaries. In the larger vessels around granulation tissue endothelial cells were seen containing from two to six "bodies" and in many of the still larger vessels cells crowded with "bodies" almost blocked the lumen. It was apparent, therefore, that they had in infection by the Leishman-Donovan bodies a type of infection in which the vascular endothelium was mainly implicated.

Dr. ALDO CASTELLANI submitted a paper entitled

Leishmania Donovani in Ceylon.

Dr. Castellani described a case in which the Leishman-Donovan [illegible] were found without the usual features of tropical splenomegaly being present. In Ceylon Dr. Castellani and Dr. Willey found in the splenic blood of rats infected with trypanosoma Lewisi structures very like the Leishman-Donovan bodies. Dr. Castellani considered it possible that the "body" was a parasite, in one of its stages of development, of the nucleus of the leucocytes—a leucocytozoon. He regarded the "bodies" as extra-corpuscular parasites of the red blood corpuscles.

Dr. LLEWELLYN P. PHILLIPS (Cairo) sent a

Note on the Occurrence of the Leishman-Donovan Parasite in Arabia and Egypt.

Dr. Phillips found the "bodies" in the splenic pulp of a Turk who had lived for a long time in Yemen in Arabia and in a man who had dwelt at Mecca. Arabia must therefore be added to the countries in which the Leishman-Donovan parasite occurred. In native Egyptians, also, Dr. Phillips had found the "bodies."

In the discussion which followed the papers upon the Leishman-Donovan bodies the following remarks were made.

Sir PATRICK MANSON warned medical men in tropical countries concerning the danger of indiscriminately puncturing the spleen in the search for Leishman-Donovan bodies. In the splenomegaly of leucocythæmia puncture of the spleen might be followed by disastrous hæmorrhage and he therefore urged careful blood examinations before splenic puncture was attempted. The presence in the disease connected with these bodies of ulceration, dysentery, or oriental sore suggested a mode of exit of the parasite. It might emerge through ulcerations and enter by insect bites. Oriental sore must now be regarded as a serious disease and sometimes leading to a general infection. He had seen a patient suffering from oriental sore subsequently develop disease of the testicle necessitating castration.

Colonel DAVID BRUCE stated that Captain Rogers's discovery of the development of Leishman's bodies into trypanosoma was a startling observation and if confirmed was highly important and it was difficult to see where a fallacy could have crept in. Colonel Bruce thought that the "bodies" ought to be known as the Leishman bodies as Leishman discovered these parasites and Donovan only confirmed the observation.

Dr. G. C. LOW (London School of Tropical Medicine) remarked that in experiments which he had made he failed to find that the parasites multiplied during incubation. At a temperature of 37° C. and room temperature the parasites entirely disappeared on the second day. In ringed fresh specimens also no changes in the parasites were found at the end of four days. The parasites were found in the macrophages or splenic cells of the spleen, in the secreting cells of the liver, in the marrow cells, and also apparently in some situations in the endothelial cells. It would be well were the "bodies" sought for in splenic anæmia. Dr. Low remarked that in view of Schaudinn's discovery of the change of an intra-corpuscular pigmented parasite (halteridium) into a trypanosome it would be well to consider the possibility of the Leishman-Donovan bodies having something to do with the resting stage of malaria. It was evident that the "bodies" existed over a vast area and were prevalent in many intensely malarial areas.

Colonel KENNETH MCLEOD, I.M.S. (retired), remarked that the hæmorrhages in Leishman disease were more pronounced than in kala-azar.

Dr. ALEXANDER CROMBIE, C.B. (London) said that pigmentation was common in cachexial fever and might be due possibly not to malaria, but to the presence of Leishman-Donovan bodies. Oriental or Scinde sores were common amongst camel-drivers and men who looked after camels. It was known that two species of trypanosoma infected camels, and it would appear that the animals infected the men who attended upon them. In districts where there were no camels there were no sores of the kind amongst men.

Mr. JONATHAN HUTCHINSON (London), Dr. J. W. W. STEPHENS (Liverpool), and Dr. LOUIS W. SAMBON also took part in the discussion.

Fleet-Surgeon P. W. BASSETT-SMITH, R.N. (lecturer on tropical medicine, Haslar), communicated a paper on

The Fungus of Tinea Imbricata.

This parasitic skin affection occurred in the Far East in the islands of the Malay Archipelago and recently it was observed in Brazil. From careful observations Fleet-Surgeon Bassett-Smith had come to the conclusion that the fungus of the disease could not be regarded as one of the trichophytons but as belonging to the aspergillus group of the perisporiacea. It differed, however, from the aspergilli in having two forms of generation: (1) by gonidia from the gonidiophores; and (2) by the development of oval spores direct from the mycelium cells The name lepidophyton (Tribondeau) should be retained for the fungus

Sir PATRICK MANSON observed that in attempts at the culture of the fungus of tinea imbricata the difficulty of obtaining scales free from fungus forms other than that in question should be borne in mind

Mr T J TONKIN (Yapton) read a paper entitled

Leprosy a Curable Disease

Mr Tonkin contended that leprosy was a disease not only markedly amenable in many of its grades to intelligent direction but one from which both with and without treatment recovery might take place At one time it was no doubt to the advantage of any community that leprosy should be regarded as an incurable ailment as thereby segregation was enforced and the only means of eradicating the disease believed in insisted upon At the present day, when knowledge was more advanced, to continue to call leprosy an incurable disease was unscientific and unnecessary to the welfare of an intelligent community There was no doubt the prevalent idea that leprosy was incurable prevented lepers coming for treatment during the early stages of the disease and thereby lessening the chances of cure It was important that the fact that leprosy was no longer regarded as an incurable disease should be made widely known and the responsibility lay with the medical profession to do so

Mr JONATHAN HUTCHINSON advocated the potency of chaulmoogra oil in the treatment of leprosy He exhibited photographs of one case in which chaulmoogra oil was given in moderate doses for nine months, the tubercular character of the skin had quite disappeared and to all appearances the patient was quite well Mr Hutchinson also related the case of a woman who recovered from leprosy and now, 25 years later, was healthy and well In Norway Danmelssen s cases relapsed when they left the asylum and went home again Mr Hutchinson ascribed the relapse to reverting to bad fish

Mr CANTLIE stated that within the past 12 months he had seen two cases of leprosy from South America In certain inland towns in South America south of the equator leprosy was prevalent in a very mild form The only signs and symptoms which appeared after, it might be, years of infection were numb patches on the legs, some whitening of the skin over the numb patch with a faint hyperæmic margin, some thickening of the nerve trunks leading to the patch, and loss of some of the hair of the eyebrows Mr Cantlie was convinced that there were many persons suffering from mild types of leprosy, showing numb patches on the lower extremity and loss of eyebrows,

ient and he
that leprosy
e arrested

Dr CROMBIE said that it must never be forgotten in speaking of leprosy and its cure that there were two kinds of leprosy—the tubercular and anæsthetic, and that in the latter the chances of arresting the disease seemed occasionally to be possible

Mr CANTLIE read a paper upon

A Liver Abscess followed by an Abscess in the Upper Lobe of the Right Lung

The patient had been operated upon in India in the early part of 1904 for an abscess of the liver On the voyage home he got a return of fever and pains in the back He had no rigors but developed a cough with expectoration of matter resembling pus from a liver abscess On May 25th on searching the liver for pus nothing was found the needle striking the scarred tissue of what was once a liver abscess On the next day pus was found in the pleural cavity a large drainage tube being inserted As the temperature did not subside a large opening was made in the chest wall when the lung was seen to be collapsed and pus flowed into the cavity from somewhere high up in the thorax The exact origin of the pus was not found until after death, when it was seen that the upper and not the lower lobe of the right lung was the seat of abscess There was no connexion between the seat of the old liver abscess which was quite healed and the abscess in the upper part of the lung In cases of the kind Mr Cantlie suggested placing a ligature round the root of the lung and removing it

Sir PATRICK MANSON and Dr JOHN CATTO (London School of Tropical Medicine) described

A New Nematode

At a necropsy in Singapore on a Chinaman who died from cholera an abnormal condition of the liver, spleen, mesentery, large intestine, and bladder was observed On making microscopic sections of the diseased tissues oval, double walled bodies (ova) varying from 68μ to 70μ long and 34μ to 40μ broad were found The ova were in enormous numbers In the large intestine they lay beneath the peritoneum and in the mucosa embryos could be seen developing inside the oval bodies In an artery of the meso rectum a minute adult nematode was visible and a free embryo was seen in a blood vessel of a mesenteric gland The parasite would seem to be an oviparous nematode of minute dimensions and of unknown species

NAVY, ARMY, AND AMBULANCE

WEDNESDAY, JULY 27TH

Major E C FREEMAN, R A M C, read a paper entitled

Camp Sanitation

He said that camps in war time fell into two divisions temporary and standing The tendency nowadays was to replace temporary camps—that was those occupied for from *24 to 48 hours only—by bivouacs, doing away with tents* altogether when on the march Standing camps were congested areas The inhabitants were crowded in their tents to an extent never met with in civil life The medical authorities should be consulted on the choice of camp sites There was nothing to be said in favour of the bell tent and a ridge pole tent was now being introduced One important point was to secure, if possible, a decent source of water supply and to take every care to keep it *uncontaminated* A system of elevated cisterns could often be improvised thus doing away with the frequent movements of water carts A great point was to teach the cooks to put all the fragments of food and so on into empty tins and not to throw everything on the ground and to trust to sweeping it up afterwards *There was a curious* tendency to put the kitchens and latrines close together The medical officer must see that they were kept as far from each other as possible If the meat was killed at the camp *the slaughter place must be half a mile or so at least away* The pail system of latrines was much to be preferred, as trenches rapidly became filled up and fresh ones had to be dug thus continually extending the danger area Under the pail system the excreta were removed from the camp altogether Refuse from the tents should be collected daily and *should be placed in a deep refuse pit outside the* camp and set fire to Cleanliness in the matter of urinals was almost impossible to attain and they must trust to the hospital *authorities to treat* all enteric fever and suspicious cases with a course of urotropin as a matter of routine before discharging them Incinerators of various patterns had been proposed for camp rubbish and excreta but it was not probable that any at all would be allowed to form part of the already too great impedimenta of an army In the general hospitals where there was a daily output of specifically infected excreta a destructor was certainly required, but such elaborate machinery should not be necessary in a camp if its *conservancy* was properly looked after and filth was not allowed to accumulate A regiment with two water sterilising machines, a portable destructor and a load of fly preventing metallic latrine seats might be healthy but it would certainly cease to be mobile Sometimes for camps in peace time the space available was small and constantly in use, as at many rifle ranges and in artillery camps connected with coast batteries Those restricted sites required special precautions, otherwise the ground became foul without opportunity to recover itself and formed a nidus for pathogenic germs Those sites should be treated more as barracks than as camps, the latrines should be permanent structures with impermeable cement floors, and worked on the dry-earth pail system There should be a pipe water supply with fixed stand pipes and iron ash bins on concrete bases should be provided for refuse, so that there should be no excuse for fouling the ground A permanent ablution hut and a shelter for the kitchen were desirable with fixed drainage channels for the waste water Every officer should be taught the *elements of hygiene* and every quartermaster on appointment should go through a short course of instruction in sanitation at Aldershot or other of the great military centres.

Surgeon-Lieutenant-Colonel P. B. GILES, A.M.R. (Bletchley), communicated a paper on

Sanitation in Volunteer Camps and the Disposal of Refuse and Excreta.

He urged that a powerful factor against efficient sanitation in volunteer camps was tha [illegible] out the camp was left to the [illegible] the entire exclusion of the medical officer and so frequently the best sanitation was not secured. It was quite true that volunteer camps were only intended to be used for a short period by the various units camping, but as it so frequently happened that favourite localities were used year after year more or less all the summer and so became foul, and because the purpose of camping was to give practical instruction, it had always seemed to him that as the dangers of camp life to a great extent were the diseases that were preventable, the proper course would be to start with all the precautions that should be observed if the conditions were actual service against a foe. It should be a *sine quâ non* that all camps should be inspected and reported upon by a medical officer before being actually laid out. Any attempts to restrict and curtail the area of a camp were risky; cramping the area of a camp might not under other favourable conditions at once show anything unhealthy but experience went amply to prove that in all localities in which camps were formed and continued certain diseases would sooner or later occur. The illnesses peculiar to camp were *de facto* such as were common to those who lived in crowded and ill-ventilated localities, and the best way to prevent those diseases was to obtain the best ventilation, cleanliness, disposal of refuse, and disposal of excreta. One medical officer as sanitary medical officer for the whole period of camp should be detailed by which one system prevailed and one standard was adopted.

Surgeon-General C. McD. CUFFE, C.B., said that the whole question of sanitation in camps had been carefully considered in the regulations and the advice of the medical officers given to commanding officers if carefully followed would usually result in the prevention of sickness.

Brigade-Surgeon-Lieutenant-Colonel G. S. ELLISTON (Ipswich) said that in volunteer brigade camps tent bottoms or floors should be supplied to both officers and men. At present in the Eastern District that was not done even in wet seasons.

Colonel J. E. SQUIRE, R.A.M.C. (Volunteers), said that the principles and practice of hygiene and sanitation should be taught to the officers, non-commissioned officers, and men, for whose benefit sanitation was so carefully studied by the medical officers of the army.

Major T. C. MCCULLOCH, R.A.M.C., said that, so far as the medical service was concerned, a complete chain of sanitary responsibility existed. The principal medical officer of a force was attached to the staff of the general officer commanding-in-chief, to whom he was to give advice in reference to all subjects bearing on the health of the troops and, with the sanction of the general officer commanding, he issued such instructions as he might consider requisite for the guidance of commanding officers, medical officers, and others. In the same way principal medical officers of divisions and senior medical officers of brigades were the responsible sanitary advisers of the officers commanding divisions and brigades, while the chain was completed when it was stated that the medical officer attached to a regiment or other unit was the sanitary adviser of the officer commanding that regiment or unit. The regulations for the army medical services indicated the scope and aim of the sanitary duties which were directed to be carried out in connexion with troops in the field. Those regulations provided sanitary inspectors for the sites of camps and of buildings to be used as quarters, hospitals, or stables, examination into the sanitary condition of towns or villages about to be occupied and their neighbourhood, the care required in collecting, storing, purifying, and distributing water for drinking purposes, the position and regulation of latrines and slaughter-houses, the disposal of refuse, the burial of the dead, and the disposal of carcasses of animals. Daily sanitary inspections of camps were directed to be carried out. Recommendations were to be made, in writing if necessary, as to precautionary measures required for the prevention of disease. When any disease was unusually prevalent every effort was to be made to ascertain and, if possible, to remove the cause, and a daily report of the progress or decline of the disease was to be continued so long as it might be necessary to do so. Those regulations also laid down that the principal medical officer of the field force was to be kept fully informed of the state of health of the troops and of the sanitary conditions of camps and other occupied places. The sanitary responsibility of the medical officer was entirely advisory in character. It was the duty of the army medical service to detail the sanitary measures which should be adopted but it was the duty of general officers commanding and of the officers commanding the various units in the field to take the executive steps to have the measures recommended carried out. With regard, therefore, to Major Freeman's point that the medical officer was seldom consulted when sites for camps were being selected, Major McCulloch said it would be observed, from what he had already said, that the matter was one which the regulations laid down the medical officer was to be consulted about, and when that was not done it was his duty to represent the matter to the officer commanding the troops. In regard to the instruction of the regimental officer and the rank and file in the elements of sanitary knowledge he wished to state that such steps were being taken. Lectures to the cadets at Sandhurst and Woolwich who were to become their future officers were now regularly given, while a more advanced course of lectures in military hygiene to officers at the Staff College was also provided. Specialist sanitary officers had been appointed for duty in England and it was part of the duty of these officers to give special instruction in matters hygienic to officers, quartermasters, non-commissioned officers, and men.

Major T. D. F. DONEGAN, R.A.M.C., then contributed a paper on the

Duties of a Medical Officer with a Regimental Unit in the Field.

He advocated that more power should be given to senior medical officers in the field in regard to the distribution of medical officers under them. He detailed their duties in the field and commented on the equipment necessary for regimental units. He recommended a reduction in drugs and discussed the advisability of having these in "tabloid" form. He exposed the faults in the present field panniers and described an operating table for field use invented by himself. The advisability of having stationary general hospitals was then put forward by Major Donegan and he also urged that general hospitals with mobility and with ample transport should be provided. The equipment of field units should be divided into ordinary, reduced, and emergency scales. He then entered into a full explanation of the faults of the present "first field dressing" and proposed that it should be carried on bandolier instead of sewn in the jacket. In conclusion, he considered the question of the ambulance transport in the field and demonstrated the necessity for two varieties of ambulances. He emphasised the necessity of having ambulance transport in first instead of second line transport, because by that means all ambulance and medical equipment wagons would be under the orders of a medical officer.

Lieutenant-Colonel A. M. DAVIES, R.A.M.C., read a paper on

Sterilisation of Infective Discharges and Utensils on Field Service.

He observed that the only methods of dealing with infective discharges in the field that were likely to be carried out in practice were: (1) burial in either deep or shallow trenches; (2) disinfection by chemicals, then burial; (3) boiling, then burial; and (4) incineration. The first and second methods were not to be recommended if the third or fourth methods were practicable. He compared the third and fourth methods and concluded that in respect to (*a*) quantity of fuel required, (*b*) degree of usefulness or extent of applicability, and (*c*) ease and inoffensiveness of working, the advantage lay on the side of moist sterilisation, where fuel was available. Where fuel was scarce deep burial, after chemical disinfection, should be practised.

Major W. C. BEEVOR, C.M.G., communicated a paper on

The Recruiting Problem.

He pointed out the vital importance of soldiers receiving a training extending over many years and suggested that boys should be enlisted for the army on the same lines as for the navy and formed into cadet companies for each regiment, brigade of artillery, or corps. He said that the increased expenditure would be compensated by saving on the poor rates, Government schools, and so on, and by the general utility of cadet companies who would be available for many duties now performed by trained soldiers and civil contractors Parents were now frequently ruined by their boys being thrown on their hands at the age of 14, 15 and 16—postal boys, telegraph boys, &c —and would be only too glad to get them into cadet corps That class of boy would develop into the best soldier A cadet company should be a separate unit in each corps, as was the case with those of the Royal Artillery, and the lads should be trained and nurtured under special supervision As each member rose to a certain standard of efficiency he would be drafted into various posts—artificers, tailors shoemakers medical assistants grooms joiners plumbers, clerks, and so on A selection should be made for the various requirements of a corps from its cadets as they grew and became efficient The question of pay and allowances should be settled on the same lines as pertained to the trumpeters of the Royal Artillery The boys parents or guardians should be required to enter into a contract with the Government, just as they would when apprenticing a boy to a trade

Deputy Inspector General T J PRESTON, R N said that parents should consent to their boys enlisting at 14 years of age and subsequently, after 18 to 12 years continuous service

Surgeon General G J H EVATT C B, deprecated the flogging of boys in the navy

Surgeon Major G A HUTTON (Leamington) said that with regard to the remarks made by Surgeon General Evatt that the boys in the Royal Navy were subject to flogging he entirely disagreed If there were any ill treatment public opinion was such in their country that that would soon be remedied

Major R C LEVER A M D, thought that they should offer men the same inducements as in civil life—permanent employment

Mr G S POLE (Middlesbrough) said it seemed to be implied that the general civil authorities did not employ discharged sailors and soldiers but though trained to rules and regulations he found them peculiarly restive under discipline and they were unfortunately unsteady, frequently immoral, and broke leave He had found marines more satisfactory

Major BEEVOR said that Deputy Inspector General Preston s statement that the best men came from the neighbourhood of London confirmed the contention that young boys from the labouring classes would give them the best men

THURSDAY JULY 28TH

Colonel D BRUCE R A M C read a paper on

Malta Fever

He said that it was one of the most tedious and refractory of fevers lasting in some cases for years and giving rise in the naval and military forces in the Mediterranean to an amount of suffering inefficiency and waste which it was most painful to contemplate Little had been done for some years past to advance the knowledge of that fever but a determined effort was being made the Admiralty War Office and Colonial Government had joined forces and under the direction of the Royal Society a research into the nature of that disease was being prosecuted Staff Surgeon E A Shaw and Surgeon R T Gilmour of the Royal Navy Dr Zammit of the Board of Health Malta Major W H Horrocks and Captain Kennedy of the Royal Army Medical Corps and Dr Johnstone of the Local Government Board were all working at the subject The micrococcus Melitensis which was discovered in 1886 was undoubtedly the cause of the fever It was a difficult micro organism to work with on account of its minute size the slowness of its growth on artificial media and the difficulty of separating it from other bacteria Of its habitat outside the body little or nothing was known It had not up to the present time been found in outside nature unless placed there artificially As to the conditions under which it could lead a saprophytic life nothing was known It was known from the statements of Bassett-Smith that cultures kept at 22° C still retained vitality after 14 months, that it lived in milk for some three weeks and in tap water for three days only In ordinary sea water it appeared to die off almost immediately Bassett Smith stated that it could live in urine from three to five days, and Horrocks gave five or six days In a dried condition it retained its vitality for much longer periods and Horrocks had made the important observation that it could live in dust for at least 69 days and on dried fabrics for a longer period. It had not, however, been found up to the present in the air or dust of infected places but that point was receiving especial attention No light had as yet been thrown on the possibility of the micro-organism having under natural conditions hosts other than man but if goats which crowded the cities and villages of Malta could grow it in their bodies and pass it out in the urine a never failing supply of infection would be present The mode of entrance of the micrococcus Melitensis into man was a subject of which they were very ignorant Did the micrococcus gain entrance by the alimentary canal the lungs tonsils, mucous membrane of the nose or eye, or through the skin? Feeding experiments on monkeys carried out by Dr A E Wright and others had been invariably negative Nothing was known of the effect of inhaling dust containing the micrococcus Melitensis but experiments were going on at present There was one case of artificial inoculation in man in which the conjunctiva was said to have been the point of entrance The smallest quantity of the virus introduced under the skin would give rise to the disease as many accidental inoculations in the laboratory testified, and that brought up the question as to whether it was possible that the disease might be conveyed from the sick to the healthy by means of biting insects although, in his opinion, it was very unlikely that it was an insect borne disease Dalton Gilmour and Bassett Smith had all attempted to separate the micrococcus Melitensis but had failed to do so He was glad however to be able to report that he received a telegram from Malta a few days ago, signed by Major Horrocks and Captain Kennedy, saying 'Found 26 colonies micrococcus Melitensis from one third c c urine That was an important observation and might be considered in connexion with the retention of vitality for long periods of the micro organism Up to the present the micrococcus had not been isolated from the sputum the expired air the sweat or the intestinal contents Another mode of exit was from the blood by means of biting insects That the micrococcus existed in the blood had been shown by Gilmour and Shaw and by Dr Zammit Gilmour especially had worked at the point and had repeatedly isolated the micro organism from the blood But up to the present the evidence went to show that it was only found in very small numbers in the blood, according to Gilmour not more than one or two micro-organisms per cubic centimetre could be found

Fleet Surgeon P W BASSETT SMITH R N (Haslar), communicated a paper entitled

The Etiology of Mediterranean or Undulant Fever from a Naval Standpoint

He stated that he had been able during the last four years to study the disease from both its clinical and laboratory aspects owing to the large number of cases invalided to Haslar annually from the Mediterranean The deductions he made from those inquiries were (1) that Mediterranean fever showed no sign of decrease in its incidence in His Majesty s Navy on that station (2) that both officers and men suffered severely but that the percentage of young officers and men in early adult age was proportionately great (3) that all ships appeared to be affected equally according to the time spent by them at Malta harbour, the permanent harbour ships giving the most cases, (4) that it was very frequently the case that men contracted the fever while in Malta Hospital when admitted for other diseases and that the nursing staff in attendance on them there showed a tendency to develop the disease but whether that was due to its endemicity or to direct infection there was no proof, (5) that the greatest incidence of cases was during the months of May and June (6) that in the fleet there was no evidence of infection being received from the shore other than through the agency of wind carried germs, (7) that the organism could retain its vitality for a considerable period when desiccated but that it died in about five days in sterile fresh and sea water and in urine but remained active long in sterile milk, (8) that the organism was very virulent in laboratory cultures readily causing attacks when taken in by the mouth or through accidental inoculation (9) that the organism was present in the peripheral blood in all cases during the early stages and in severe pyrexial relapses and that in the afebrile intervals and following cachexia it was not demonstrable but that in no case was it very abundant, (10) that the disease might remain latent for several months and relapses might occur for a period of two years at least but that when once completely cured it gave an immunity from further attacks, and (11) that though infection by means of blood sucking insects was possible, the evidence would lead to the belief that in the presence of bad sanitation where the disease was endemic infection was probably conveyed in dust by winds mostly in the hot dry months following the rains, and that it gained access to the patient through some breach of surface, probably in the throat, and that, as a rule, when perfect health had been established after an attack of the fever, an immunity was acquired against further infection.

Professor S. GRECH said that as a general practitioner in Malta he was glad to make a few remarks. He protested strongly against the nomenclature—Malta fever; it might give to Malta a bad name which might keep away winter visitors. That same fever had been observed in Sicily, Naples, and all the other towns along the Mediterranean.

Major T. H. F. CLARKSON, R.A.M.C., and Deputy-Inspector-General PRESTON having spoken, Colonel D. BRUCE replied.

Fleet-Surgeon JOHN LLOYD-THOMAS, R.N. (Portsmouth), read a paper entitled

A Naval Surgeon's Notes.

He drew attention to some points which concerned the naval surgeon and were incidental to modern methods of big-gun firing at sea. He thought the ear suffered more damage from big-gun firing than any other part of the body. He briefly considered the part each section of it played in conveying air vibrations. If a typical case of ruptured membrana tympani were seen immediately after the accident from gun fire smart local pain was complained of and the auroscope revealed a minute fissure with red raw edges and a drop of blood at its lower end. If the ear were merely plugged with wool and boric powder, the patient being at the same time sheltered from further concussion, the drum healed by first intention. "Irreparable deafness," commonly called "gun deafness," was a condition regarding the pathology of which too little was known. It existed with or without any visible sign, such as rupture of the drum, and both sides of the head were generally equally affected. Tinnitus was a very common subjective symptom. The outer ear revealed nothing when the drum was intact. The Eustachian tube might be quite patent. The deafness varied in degree but was seldom, if ever, complete. It was to be regretted that up to the present no device had been found that would sufficiently protect the ear from the violent concussions caused by the modern gun. To protect the membrana tympani cotton-wool was useful as diminishing the violence of the air waves proceeding in its direction, and for some time a doughy substance had been largely used for plugging the external meatus and it was recommended to keep the mouth slightly open. Experiment showed that if the irregularities of the auricle were filled with wax or oil the intensity of sound was weakened, and he had advised vaseline to be tried for this purpose but with doubtful results. Nipple-shaped india-rubber plugs had been used. The direction of the meatus externus to the source of sound was material. If the side of the head was directly opposite to an explosion the ear would suffer a more violent concussion than if the full face were opposed to it. A gun's crew, however, were so variously disposed that no definite lines could be laid down for observance.

Surgeon-Major C. R. KILKELLY, C.M.G., followed with a paper on

The General Hospital in War: its Working and Staff.

War hospitals were of three kinds: the field, stationary, and general hospitals. A field hospital was essentially a mobile unit. Stationary hospitals were improvised constructions scarcely deserving the name of hospitals. They were of the nature of rest camps, detained wards, or converted field hospitals. General hospitals were established to receive all kinds of sick and wounded evacuated from field hospitals to treat and care for them in accordance with the latest and best methods of modern science. It was impossible to predict what kind of cases or in what numbers sick and wounded would be sent to a general hospital. It must therefore be capable of expansion in all its parts and capable of sorting and receiving the various groups of diseases in appropriate wards or specialised sections. Hospitals were often suddenly required at places where hitherto stationary hospitals had been established, owing to the outbreaks of epidemics, the formation of standing camps, or as a preliminary step to the formation of a general hospital, and a general hospital should be able to detach one or more complete sections for work at such places if within the region of its "sphere of influence." In order to combine efficiency with economy the model general hospital should be organised on about a 550-bed basis (500 beds for non-commissioned officers and men and 50 for officers), capable of being doubled or trebled in size, divided up into appropriate sections, and with a convalescent camp attached. In regard to equipment he had found the new pattern tortoise tent 20 by 24 and the Indian pattern E.P. tent the most suitable. The present hospital marquee was a most defective tent; it was heavy, of a bad shape, and easily blown down by a gale of wind. The equipment generally should be carefully selected and constructed in "standardised" patterns. The Red Cross committee could do useful work in that line by obtaining and exhibiting selected standardised patterns of equipment and arranging with firms to supply them at short notice. The equipment must include in an efficient general hospital a destructor for burning refuse and utilising the heat to generate steam in a boiler. The steam could then be utilised in a disinfector for disinfection by saturated steam under pressure and also in a turbine engine and dynamo for electric lighting, x-ray work, cooking, baths, and sterilising milk.

Dr. S. HAMILTON (Newport, Mon.) read a paper entitled

Is the Widespread Slight Training in Ambulance Work Beneficial to the Community or would it be better to make the Training more thorough at the Expense of Numbers?

In the course of his remarks he suggested that it should be an instruction to all examiners to make the examination more testing on the practical application of first aid; that those interested in ambulance work should be urged to organise divisions or corps of the St. John Ambulance Brigade in towns where none already existed (this would bring the certificate holders in these towns together for practice once a month and thus keep them efficient); that the St. John Ambulance medallion should be given only to those certificate holders who afterwards joined the brigade and passed the annual examination—the service badge and the service medal of the St. John Ambulance Brigade should be continued under the regulations at present in force; and that factory owners and large employers of labour in towns where ambulance classes were held should be invited to offer challenge cups for annual competition which would be a great stimulus to the various ambulance teams to keep in training.

Mr. POPE thought in regard to ambulance work that the chief defect of the system was the laxity of the examiners who did not carry out the practical part of the examination thoroughly and who passed candidates too easily.

Dr. C. H. MILBURN (late Deputy Commissioner of the St. John Ambulance Brigade) thought that wherever a general hospital and a brigade unit existed in the same town opportunities should be provided for giving the ambulance men, under proper control, instruction and practice in systematised general nursing and orderly work. On the question of giving a large number of men a slight knowledge of first aid or a smaller number a more thorough training and education in ambulance work he thought that every recruit on joining the services should receive some first-aid instruction but that the men of the Royal Army Medical Corps should have the most thorough and extensive education possible.

Deputy-Inspector-General PRESTON said that the St. John Ambulance Brigade men were more efficient than Association men as they kept up their work and were qualified in nursing. The Admiralty had at present preferred Brigade men as being better trained.

FRIDAY, JULY 29TH.

Staff-Surgeon F. H. A. CLAYTON, R.N., sent a paper on

The Organisation of the Treatment of Syphilis in the Navy.

He suggested that men who had contracted syphilis should have the consequences of their misfortune impressed upon them by giving them a small pamphlet of advice, and by proper care of the teeth and so on should so far as possible be prepared both for combating the disease and for preventing any ill-effects of mercury; that their attendance for observation and treatment should be made part of routine both in ships and shore establishments and proper records of attendance kept; and that such records should include the dates and nature of symptoms and treatment and any other points of value in order that, to insure continuity, the requisite information might be sent with the patient on transfer to another ship.

Colonel SQUIRE contributed a paper on

The Organisation during Peace of Civil Medical and Ambulance Aid to insure an immediate Reserve of Trained Assistance on the Outbreak of War

He said that in a war of any magnitude it was necessary to supplement the military organisation for the care of the sick and wounded by civilian aid Such aid was essentially of two kinds—surgeons nurses and orderlies receiving pay through the War Office and *personnel* and stores provided by voluntary subscription Voluntary aid might be wasteful if no regulations for its employment had been previously laid down Organisation during peace was essential to insure the best provision in war The Central British Red Cross Committee had been instituted as the organising body for civilian aid with troops in war Surgeons and nurses adequately trained in their professional work were to be obtained in sufficient numbers to allow of selection but in order to obtain at short notice the best professional aid selection must have been made previously A list should therefore be kept at the War Office of suitable persons willing to serve if required A roll of men willing to serve as orderlies might be kept in the same way, the special qualifications of each being entered against his name Conditions of service and a scale of pay for the various duties should be laid down For the *personnel* serving under some authorised voluntary aid society or committee the conditions of service and rates of pay would be drawn up by the body engaging their services but would have to come within the terms of requirements previously formulated by the Central Red Cross Committee and communicated to the body offering aid Hospital equipment surgical stores, medicines and so on were needed in war greatly in excess of peace requirements Many of these were perishable and could not with advantage be kept in store By previous arrangement with large firms almost everything needed could be procured as required What was necessary was a list kept at the War Office of firms able and willing to supply materials The supply of comforts both for the troops in the field and for patients in hospitals came within the scope of voluntary, aid A list of articles which would be especially acceptable should be drawn up and sent to all applicants at the beginning of a campaign The organisation of that department and the storage and distribution of those

organised equipped and maintained by voluntary subscriptions under regulations to be drawn up previously by the Central Red Cross Committee Voluntary efforts should also provide assistance to the sick and wounded whilst journeying along the lines of communication and on arrival at the base or at home Accommodation at suitable places should be arranged for convalescents at home All those matters required carefully arranging and organising beforehand and it was essentially the duty of the permanent voluntary aid societies—such as the Red Cross Society—to perfect such organisation during peace It was desirable that there should be some organisatioi
country, by means of which
a war broke out could at oi
central body which was in
War Office These local committees should be permanently established under some central organisation—preferably not connected with the War Office—with its head office in London As the basis on which to build up the organisation that was required they had the British Red Cross Society (British National Society for Aid to the Sick and Wounded in War) the St John Ambulance Association the St Andrew Ambulance Association various nursing associations and, since 1898 the British Central Red Cross Committee The British Red Cross Society, founded during the Franco Prussian war in 1870 hibernated during periods of peace and only woke to activity when a war broke out, instead of spending the leisure time of peace in organising for war The St John Ambulance Association, primarily originated to provide instruction in first aid treatment in case of accidents in civil life had comparatively recently considered the possibility of providing supplementary aid to the troops during war, but when the South African war commenced it had made no provision for training in the duties required by orderlies and nurses for military service Nevertheless the association was able to furnish a large number of willing, though imperfectly trained, men to the army in South Africa The St John Ambulance Association was now officially recognised by the Central Red Cross Committee as a body from which hospital *personnel* could be obtained during war Where the present machinery for the organisation of civilian aid seemed to be faulty was in the chain of connexion between the War Office on the one hand and the public which supplied the *personnel* service money, and gifts which the War Office would utilise in war on the other The Red Cross Society and the various ambulance associations were private organisations independent of the State machinery The public had not always been in exact accord with *army methods of organisation and might possibly* be more disposed to send money and gifts to the troops through some organisation outside the army than through a committee directly connected with the War Office The representation of certain organisations (Red Cross Society and St John Ambulance Association) on the Central Red Cross Committee seemed
should be avoided
Red Cross Commi
members—should
on the requirement
voluntary aid could be accepted by the army but leaving it to a voluntary society to organise and provide the aid The committee of that society would be the one and only means of communication between the various voluntary aid societies and individuals offering aid and the War Office When war broke out the officials at the War Office, who had their hands full with the work of mobilisation and all that that entailed, would not then have its time occupied with the various suggestions and offers of help of the different societies &c, but would be relieved of that by the committee The British Red Cross Society seemed to be the body which should *organise the voluntary aid during peace and it should establish* local centres throughout the country In war time it might well carry out the duties allocated to it by the Central Red Cross Committee in its present regulations one of the most important of those duties being the collecting and distributing of funds The main thing required at the present time was the organisation of local committees throughout the empire by means of which individuals and societies offering help in time of war might be brought into touch with the Central Red Cross Committee representing the army The Central Red Cross Committee was considering the matter But the Central Red Cross Committee was not the best body to undertake the work it should be in communication with one other committee only not with many which would multiply its work and correspondence when war broke out A single buffer committee purely civilian, should stand between the Central Red Cross Committee and local committees or individuals The proper body to take that important position was obviously the British Red Cross Society The British Medical Association, with its branches all over the empire might well serve as a means of forming a truly Imperial Red Cross Society Through the British Medical Association it would be possible to find a medical man in
India an
for his
organising committee in London would bring all into touch and with *representatives of the National Aid Society* St John Ambulance Association, and similar bodies would form the direct communication with the Central Red Cross Committee The latter committee would decide upon the requirements it would be for the new committee (Imperial Red Cross Committee) to see that those were forthcoming when needed

Major FREEMAN said that having had the honour of being registrar of a general hospital for 17 months in South Africa where *their whole staff except 20 men consisted of* volunteers and St John Ambulance Brigade men, he was very glad to have an opportunity of paying a tribute in that section to the conduct of those men in the field, they worked quietly and unostentatiously, and died, too in the cause of humanity during those months of pestilence in Bloemfontein, and their work had received scant public recognition The volunteers were the most useful because they stayed with them all through the campaign The St John's men were perhaps better trained but they stayed too short a time

Major McCULLOCH said that urgent need existed for a thorough organisation of the voluntary aid resources of the have the only certainties which life affords. By the aid of these certainties eclipses are predicted and ADAMS and LE VERRIER were enabled to announce the existence, and to discover the position, of the previously unknown planet Neptune. The changes of view discussed by Mr. BALFOUR have no reference to phenomena but only to the conditions of the matter through which phenomena are displayed, and they have at present absolutely no bearing upon the practical conduct of life. They neither strengthen nor weaken the case against the departmental officials responsible for the equipment of our troops, and they must not be employed as furnishing an argument against the utility and applicability of science in man's dealings with his environment. It is this homely and practical aspect of the case which the Guild must endeavour to force upon the attention of the public, and it is neglect of this aspect which has been the cause of incalculable sickness and mortality, of innumerable failures afterwards retrieved, if at all, only by prodigality of treasure and of life.

◆

The Metropolitan Hospital Sunday Fund Collection.

THE report of the distribution committee of the Metropolitan Hospital Sunday Fund for 1904 and the discussion which followed its presentation at the meeting on August 9th raise several questions of great social and medical importance. There has been a marked tendency in late years for the Fund to increase. The public, led so earnestly by His Majesty the KING, by an unfailing succession of sympathetic Lord Mayors of London, and by constant efforts on the part of the various ministers of religion, have been aroused to a deepening sense of responsibility. It is only right, too, to say that the energy of the secretary of the Fund and his inventiveness in devising new forms of appeal have contributed not a little to the growth of the Fund; nor must Mr. HERRING'S splendid generosity be forgotten. It is painful, therefore, and a little surprising to have to notice for 1904 a falling off of £2000 in the amount to be distributed, and to think that this means so many hundreds a year less to the numerous hospitals and dispensaries by which the benevolence of the public to the sick and wounded poor is administered. There should be much searching of heart among the different sections of the community as to the blame for such a falling off. There is a ready and offhand excuse—we have heard it—"Times are bad, trade is depressed, dividends are low, property is depreciated." Such statements cannot be contradicted, but they are entirely inadequate as an excuse for pinching and starving the hospitals. There is a time to make money and there is a time to spend it. It is the advantage of a country like this that there is always a reserve of wealth practically unaffected by the fluctuations of trade; whole classes of our population are conscious of little or no abatement in their luxuries. It is not to these classes alone that we must look for the better support of our hospitals, and some speakers at the Mansion House thought that the strength of the Fund lay in the support of all classes. But it takes a GUY to make a Guy's Hospital. Very little imagination will show that the poorer classes cannot do much for the maintenance of our great hospitals and that the gold for this must mainly come, and should come, from accumulated wealth—from men with reserves. We have a faith in the generosity of rich men which leads us to believe that if only they can be assured that our hospitals are well and carefully administered they would out of their abundance adjust the adverse balances that so harass those who have to find the ways and means to keep hospitals open. Heaven forbid that we should seem to belittle small contributions. As has been pointed out more than once in our annual supplement a voluntary rate of one halfpenny paid by the metropolitan public would at once more than double the amount of the Fund. But this universal feeling of indebtedness to our great charities is not in the least likely to take place, and for practical purposes it seems that we must look expectantly to individual efforts.

The attention of the councils of the great hospital funds—King Edward's Hospital Fund for London and that of the Metropolitan Hospital Sunday Fund—has been much given of late towards the double end of making hospitals efficient and of moderating the rate of their expenditure. The distribution committee of the Metropolitan Hospital Sunday Fund, in the report for 1903, said that "its special attention had been directed to the constantly increasing expenditure of hospitals in the maintenance of patients," and showed how this expenditure in ten years had increased in 21 of the principal hospitals at the rate of *4s. 3½d.* per week per occupied bed. The committee reverts to the subject in its recent report and shows that it is as determined to compel economy in hospitals as to urge liberality on the contributing public. Happily, it is already able to report that after conferences with some of these hospitals considerable reduction of expenditure has been effected. It is only fair to say that the rate of expenditure of our general hospitals in point of economy will bear a favourable comparison with that of those hospitals which have the deep pocket of the State to rely on for their support. This is well shown in the very interesting report of the managers of the Metropolitan Asylums Board for 1903. Enteric fever is one of the most expensive diseases treated in general hospitals, but it appears that the cost of treating such patients in the hospitals of the Board compares unfavourably with the cost for the same public service incurred by the general hospitals which are maintained by voluntary subscriptions. The council of the Metropolitan Hospital Sunday Fund has made rules which are meant to reduce the abuse of the out-patient department and which have had some success. There is still room, however, for much more care in the work of this department. A glance at the admirable statistics of the Fund will show that there is great variation in the different hospitals in this respect, some expending only 1*s.* 6*d.* per head on each out-patient, others, as the Cancer Hospital, spending 30*s.* But a more important point in genuine economy than cutting down the expenditure per head in the treatment of out-patients is the efficiency of means used for the exclusion of persons who have no claim on the charity of the public. The Metropolitan Hospital Sunday Fund will do well to use its influence to curtail the proportions of the overgrown out-patient departments of hospital work, especially in the way of discouraging expenditure on huge building operations and the admission wholesale of unfit persons. The out-patient departments of our hospitals ought to be reserved strictly for the sick and injured poor. The work of the general practitioner should not be discharged there gratuitously to the benefit of well-to-do people.

Not altogether unconnected with the question of economy is the action of the Metropolitan Hospital Sunday Fund in withholding its grant for this year to the City Orthopædic Hospital, Hatton Garden, which in point of mere numbers is more important than the other orthopædic hospitals with which amalgamation is being recommended. On general principles the authorities charged with the distribution of the Fund deprecate the multiplication of special institutions. The premises of the hospital are not model ones for hospital purposes and are not situated in a locality favourable for the pure air and light treatment of a set of cases which peculiarly need such advantage. There is much to be said for one large metropolitan orthopædic hospital, with a country branch to which suitable cases could be sent. But the withdrawal of the grant from the City Orthopædic Hospital, against the management and financial conduct of which not a word has been said as far as we know, has necessarily caused much pain, while the letter which we print in another column from Mr. J. A. Phillips makes out a good case for the institution. We know what pains the distribution committee takes in respect of the awards, and feel that criticism may seem ungracious towards its delicate work, but we have come to the conclusion that, at any rate temporarily, the City Orthopædic Hospital should have received a grant.

The Physiological Aspect of the Administration of Chloroform.

In the Section of Physiology at the British Medical Association, a most interesting debate upon the subject of chloroform anæsthesia was introduced by Sir Victor Horsley, and a short record of the views of the many well-known speakers was published by us last week. We hear from various sides, and not infrequently, that the employment of chloroform as an anæsthetic is destined to diminish, though some practical anæsthetists do not hold this view. Chloroform as an anæsthetic has certainly earned the unenviable reputation of being "dangerous," yet there are many with a right to be heard who assert that not only is chloroform the most effective anæsthetic but that attention to certain rules can minimise the dangers of its administration to vanishing point. Whether or no its administration is becoming less and less resorted to, it is undoubtedly true that never have the administration and action of the drug been more rigorously subjected to investigation than at the present time. The task set before the anæsthetist when he is required to produce deep anæsthesia with chloroform is one more difficult than those who set him the task seem sometimes to picture to themselves. The channel along which the administrator of chloroform is asked to steer the life of the patient is a very narrow one. He has to employ a powerful poison which acts upon all the nerve cells of the brain and spinal cord, and at the same time the nerve cells of the respiratory centre and the nuclei of the inspiratory muscles have to be safeguarded. This is, at any rate, the physiological theory, and physiologists premise that the chemistry of nerve cells differs from cell group to cell group. If sleep is held to furnish a rough example of what is required in chloroform anæsthesia, the distinction which the chloroformist is required to observe with his drug between the respiratory nerve cells and the rest of the nervous system is one that, were it not safely accomplished over and over again, might seem impossible from *a priori* considerations. For chloroform narcosis differs from sleep in this, chloroform is a "protoplasmic poison" potent to destroy life in every kind of living cell.

Assuming that the selective effect required in surgical anæsthesia is only a particular depth in a steep gradient of chloroform depression the lowest stage of which is death, it would follow that safety lies in perfect grading of the dosage. But not only is dosage in the administration of chloroform a very different thing from the simple dosage of a drug introduced by ordinary methods into the bulk of the body, but practical anæsthetists are not agreed that the solution of the matter lies entirely in the question of dosage. The first essential for accurate grading of the dosage is thorough knowledge and control of the percentage of chloroform vapour in the inspired air combined with normal freedom of expiration. These requirements are met, it is claimed, by an inhaler recently devised by Mr. Vernon Harcourt, the distinguished chemist, which delivers to the patient a percentage vapour of chloroform in air, the maximum tension of which is 2 per cent. It is claimed that in ordinary circumstances this concentration of the vapour suffices for surgical anæsthesia. The induction of the narcosis may then be slow but that need not be a danger, for it has recently been suggested by experiments upon the isolated heart with certain artificial circulating fluids, that the mode of action of chloroform is not cumulative. Depression of the heart beat is a salient effect of chloroform action when the drug is "pushed." Whether this is due to a direct action on the muscle or on the network of nerves in the heart wall is not at present clear. The fact remains that the heart's activity is easily depressed by chloroform. Yet, even when the action has been pushed to extinction of the beat and maintained at that point for half an hour at a time, the experiments of Professor Sherrington and Miss Sowton show that, on allowing fresh blood in place of that containing the chloroform to flow through the coronary vessels, the beat in a few seconds reappears and in a few seconds more regains its unimpaired activity completely. The cardiac danger, therefore, in chloroform narcosis, though grave, offers the favourable feature that mere continuance of the depression does not aggravate it, at any rate when low percentages are being dealt with. Mr. Vernon Harcourt's inhaler, however, though so ingenious and so highly commended by many observers, has not escaped criticism from the mechanical point of view.

An interesting paper by Professor B. Moore and Dr. H. E.

ROAF was read to the Section of Physiology as a contribution to the debate. These observers propound the thesis that chloroform combines with proteid radicles of living matter in a compound which is readily dissociable. Finding, as others before them, that chloroform is absorbed by blood in larger measure than by water or saline solutions they have devised a method of reading directly the pressures it exerts in the two fluids. They find that the tension exerted by a given quantity of chloroform in blood is less than its tension when dissolved in water or physiological saline solution. They urge that it combines with the blood proteids. This view is in antagonism to the view of Professor OVERTON, who refers the predominance of nerve effects in chloroform action to the high solubility of the drug in fatty compounds, such as the lecithin of nerve fibres. But these fats are not the immediately active part of the nervous mechanism and it is difficult to see how on OVERTON'S views the immediateness of the action of the drug, both in regard to onset and recovery, can be explained. On the other hand, the view of the production of an easily dissociable combination between chloroform and forms of proteid agrees well with a fact taught by the work of SHERRINGTON and SOWTON. When administered in blood instead of physiological saline solution the amount of chloroform which can be given to the heart without depressing its action is increased twelve-fold. It may be that the capriciousness of action which seems at present to attach to chloroform, as to so many of the drugs of which we are compelled to make daily use, will through patient inquiry be traced to sources controllable by practical means. If so we shall certainly witness a return to wider confidence in the employment of an effective and convenient anæsthetic.

◆

The Hospital Isolation of Scarlet Fever.

THE desirability of isolating certain forms of communicable disease has been in some degree recognised almost ever since the dawn of history, and within the last 40 years the practice has undergone such extension that some members of the medical profession are now asking whether it is not being carried too far. Great variations, of course, exist in the conditions which have to be provided for. Enteric fever and small-pox, for instance, are comparatively rare in children, while scarlet fever, measles, and whooping-cough are comparatively rare in adults. Enteric fever invariably requires prolonged confinement to bed and attentive nursing. Small-pox may be rendered so mild by previous vaccination that the eruption is limited to three or four tiny pustules and the patient does not feel himself to be unfitted to follow his ordinary employment for more than a day or two, whereas on the other hand hardly any patient can be more helpless or more in need of careful nursing than one suffering from the confluent form of the disease. The necessity of hospital accommodation for enteric fever and small-pox may therefore be regarded as unquestionable. Exceptional diseases have also sometimes to be provided for. We believe that the Metropolitan Asylums Board commenced its hospital work with the acquisition of a site at Hampstead and the erection of temporary wards in 1869 for the treatment of relapsing fever, a disease which has not been seen in this country since 1873. In London diphtheria did not attain considerable proportions till within the last 20 years and during the same period typhus fever, which was formerly prevalent, has disappeared. Measles and whooping-cough, though productive of a considerable mortality, have never been treated in hospitals on an extensive scale. It is mostly with regard to the isolation of cases of scarlet fever in special hospitals that a diversity of opinion exists among medical practitioners.

At the Congress of the Royal Institute of Public Health held at Folkestone last month a discussion on this subject was opened by Dr. C. KILLICK MILLARD, medical officer of health of Leicester, and a number of medical officers of health took part in the proceedings. This phase of sanitation has during the past eight or nine months received considerable attention. The utility of isolation hospitals was questioned in our columns some five years ago by Mr. E. D. MARRIOTT of Nottingham, but few medical men supported him in a contention which seemed to imply that isolation hospitals were valueless in the case of all infectious diseases. In 1901 Dr. MILLARD read a statistical paper before the Incorporated Society of Medical Officers of Health on "The Influence of Hospital Isolation in Scarlet Fever." On this occasion the following motion was proposed: "That as the hospital isolation of scarlet fever has now been tried for a number of years the time has arrived when a full inquiry into the subject is desirable." The meeting, however, declined to vote on the motion. The same writer read a paper six months later at a Congress of the Royal Institute of Public Health held at Folkestone and a similar motion to the above was defeated by 70 votes to 40. After this the question remained in abeyance until October, 1903, when Dr. A. MEARNS FRASER, medical officer of health of Portsmouth, chose the subject for his presidential address to the Southern Branch of the Incorporated Society of Medical Officers of Health under the title of "Is the Hospital Isolation of Scarlet Fever worth while?" Subsequently, both in our own columns and in those of other medical journals, the question has been freely debated, and after discussion at the recent Folkestone Congress the following motion was carried by 36 votes to 20: "That as the hospital isolation of scarlet fever has now been tried on a large scale for a number of years, and as some doubt exists as to whether the results obtained are commensurate with the cost, it is desirable in the public interest that a full and authoritative inquiry into the subject should be held."

So far as we can gather, the main arguments advanced by the opponents of the system are (1) that no town which isolates habitually a very large percentage of its cases of scarlet fever in hospital can show any greater diminution in the attack rate of scarlet fever than those towns which isolate very few or none of their scarlet fever cases; (2) that isolation in hospital does not prevent the spread of the disease, inasmuch as it is recognised that, in spite of the greatest care, cases discharged from isolation hospitals, to all appearance free from infection, frequently spread the disease on their return home; (3) that as regards the patient himself he has in most cases as good, if not a better, chance of making a recovery at home as in hospital, and (4) that the type of scarlet fever at present in this country is a mild one with a very slight mortality, the mildness of type having arisen quite independently of hospital treatment. The isolation method of dealing with scarlet fever has, however, very competent and strenuous defenders who make out a good case in its favour on medical and statistical grounds. In particular the upholders of hospital treatment combat the idea that cases can be as well looked after in the average home as in a special hospital. There is in the isolation hospital a small risk of contracting other specific diseases, but this is the only point where hospital treatment seems at fault in comparison with treatment at home. The issues raised are complex, but we think that a case is made out for inquiry, and hope that that inquiry, if instituted, will be conducted without any introduction of personalities.

Annotations.

"Ne quid nimis."

THE NEW SYDENHAM SOCIETY.

THE forty-sixth annual meeting of this society was held in Oxford on Friday, July 29th. The President, Professor William Osler, presided and there was a large attendance of members. The honorary secretary read the report of the council and submitted the balance sheet and proposed list of officers for the ensuing year. The officers were elected by ballot, Professor Osler being elected president, Mr. Henry Power treasurer, and Mr. Jonathan Hutchinson honorary secretary. The adoption of the report was carried unanimously and among matters mentioned therein was an interesting statement regarding the Clinical Atlas now in course of publication by the society. The council had suggested that the issue of the Clinical Atlas should be prolonged indefinitely and at least four fasciculi are to be published in every year. The report stated that it would be the endeavour of the editors to make each fasciculus and, as far as possible, each plate complete in itself, but it was not to be considered that any of the subjects illustrated were finally dismissed or considered complete. As regards the publication of printed volumes it was hoped that in addition to the four fasciculi a year the funds may soon afford the publication of a printed volume yearly. These volumes would be devoted to collections of the most important monographs recently published, especially selecting such as dealt with topics which had been published in the atlas. The council further stated that a considerable increase in the members' list would enable the publication of the atlas to proceed much more rapidly. Professor Osler said that he regarded with great satisfaction the proposal that the issue of the Clinical Atlas should be prolonged indefinitely, for he felt that this work would prove of the utmost value to all engaged in the practice of our profession both at home and abroad. We can cordially endorse Dr. Osler's words, for the value of the works published both by the Old and the New Sydenham Society is inestimable to members of the medical profession. We can only hope that the desire of the council for an increase of membership will be realised.

THE SOUTH AFRICAN MEDICAL CONGRESS.

THE South African Medical Congress will be held at Pietermaritzburg, Natal, in June, 1905, under the auspices of the Natal branch of the British Medical Association. The preliminary arrangements are nearly complete. A large general committee has been formed with two subcommittees—(a) financial and social, and (b) sectional. The work of the congress will be split up into the following sections: (1) Subjects of General Interest; (2) Medicine; (3) Surgery; (4) Gynæcology and Obstetrics; (5) Public Health; and (6) Special. The list of office bearers is not yet settled but the following offices have been filled: President of the Congress: Dr. James Hyslop, D.S.O., Lieutenant-Colonel, Natal Medical Corps, superintendent of the Natal Government Asylum, Pietermaritzburg. Vice-President of the Congress: Dr. Samuel G. Campbell, Durban. Joint general secretaries: Dr. D. Campbell Watt, Pietermaritzburg, and Dr. W. Watkins Pitchford, Government Laboratory, Pietermaritzburg. Treasurer: Dr. W. Russell Strapp, Pietermaritzburg. Secretaries of sections (all resident in Pietermaritzburg):—General subjects, Dr. A. I. Fraser; Medicine, Mr. H. N. R. Child; Surgery, Dr. W. J. Woods; Gynæcology and Obstetrics, Mr. H. S. Flook; Public Health, Dr. O. J. Currie; and Special, Dr. R. A. Buntine. Personal invitations will be issued to all medical men in British South Africa, and those who desire to read papers are asked to communicate with the sectional secretaries. The presence at the congress of medical visitors to South Africa will be highly esteemed.

IN THE MATTER OF PATENT MEDICINES.

WE have received a long letter from a correspondent who has read with disapproval our article in THE LANCET of July 9th, p. 98, which bore this title and referred to the question of protecting proprietary medicines by letters patent. Our correspondent claims to have obtained this protection for a "powder" which he advertises as "a remedy against deranged stomach, cold in the stomach (acute or chronic), diarrhœa, dysentery, cholerine, cholera, and all other diseases consisting in and caused by fermentation or putrefactive processes in the stomach and in the intestines, further, against defectibility of blood formations and morbifically altered condition of the blood (infectious diseases) such as typhus, pneumonia, consumption, &c." Our correspondent considers that "the infringement of letters patent rights by men who cannot at least prove its invalidity is a mean fraud," and that the medical man who gives a prescription identical with the patented article is "counterfeiting the patented remedy." He adds: "You don't consider, as it seems to me, that the patient himself can be very well in the position to make his own observations and reflections on his sickness and to make on his own body experiments which lead him to such a discovery especially if the remedies of physicians did not have any result and if the patient possesses some knowledge of chemistry." We omit the details given of the composition of the particular remedy under discussion and for the sake of argument we assume that the statements which we have quoted are literally true. Even then, however, we cannot agree with our correspondent's opinions and prefer to adhere to our own. We regard the making of experiments upon their own bodies by patients as highly undesirable, whether they are made with "patent medicines" or otherwise. We consider that if medical science can discover new drugs and uses for them, or for old ones, of benefit to those suffering from disease, it is contrary to public policy and to the interests of suffering men and women that any monopoly in such drugs or their uses should exist for the pecuniary benefit of individuals. The Patent Acts do not contain anything forbidding such a monopoly but, fortunately, there are practical difficulties in the way of its creation and maintenance. The person who registers any invention in order to secure patent rights for it does so at his own risk, and the Patent Office neither knows nor cares whether his invention is a novelty such as would be a fit subject of a patent or not. As a matter of fact a few medicinal compounds are "patented" every year, but in the majority of cases a device or title is chosen which can be registered as a trade-mark and nostrums are advertised under and become associated with it. Other persons can thus be restrained from passing off their goods by means of any imitation of the trade-mark or "make up" which has become known to buyers as distinguishing goods of a particular kind. The supposed protection of a formula so that it may not be used by a medical man in prescribing for his patients is a bogey which, as a rule, may be disregarded. If a practitioner's medical knowledge informs him that a certain combination will be of use to his patient he need not be deterred from prescribing it by the fact that another person claims an exclusive right to manufacture it. Among the practical difficulties which, we are glad to say, exist to prevent monopolies in medicinal compounds are others besides the question of the validity of the patent rights. We would ask any who claim such rights against whom they would proceed for a supposed infringement of them. Would they sue the medical man who prescribed the medicine, the druggist who compounded it, or the patient who purchased and took it? Supposing that they could prove their facts, a matter of some difficulty, what remedy would satisfy them? Would they claim damages or an injunction? Would they ask for an account of profits or for what? And lastly, what good would any of these be to them?

THE CHAIR OF PATHOLOGY IN THE UNIVERSITY OF MANCHESTER.

THE University of Manchester has taken many important steps in the arrangement and selection of its professorial staffs. The great subject of chemistry is now represented by two professors—not to speak of many lecturers—one for inorganic and the other for organic chemistry. The subject of pathology also now calls for two professors. Formerly this subject was ably taught by Professor J. Dreschfeld, now professor of medicine. In 1891 the chair was endowed by the Proter trustees and Dr. Sheridan Delépine was appointed professor. During these 13 years the subject has grown not only in importance but extent. Bacteriology has developed at an ever-increasing rate, both in its relations to medicine and public health as well as in relation to the prevention of disease. Besides carrying on the work of the pathological department proper Professor Delépine devoted much energy to the foundation and advancement of a school of public health. Now, and for some years past, there has been a separate laboratory of public health under the direction of Professor Delépine, and in October next it is hoped to open an entirely new laboratory which, at a cost of about £10,000, is being erected on a site near to where the new Royal Infirmary will be erected. It thus became evident that some rearrangement of duties should be made for the staff of the pathological department. About a year ago the council of the then Owens College appointed Professor Delépine Proter professor of comparative pathology and bacteriology. This left the chair of pathology and pathological anatomy vacant. After full deliberation the council of the University appointed Professor J. Lorrain Smith, Musgrave professor of pathology in Queen's College, Belfast, to fill the chair of pathology and pathological anatomy. Professor Lorrain Smith was appointed lecturer on pathology in Queen's College about ten years ago and professor in 1901, when the lectureship was raised to a professorship owing to its endowment by the late Sir James Musgrave. Professor Lorrain Smith is a graduate in medicine of the University of Edinburgh; and has been John Lucas Walker student in pathology in the University of Cambridge. To his pathological experience he adds a requirement of great importance—that of having acted as a resident physician in a large hospital, the Royal Infirmary of Edinburgh. Professor Lorrain Smith's original contributions to certain departments of the borderland between physiology and pathology are well known. He has worked on the effects of thyroidectomy, the oxygen-tension of blood in health and disease, the effects of air vitiated by respiration, the oxygen capacity of the blood in anæmia, and on more purely pathological questions in connexion with typhoid fever. We congratulate the University of Manchester in thus providing liberally for the prosecution of pathology in all its branches and applications.

THE WORK OF THE GOVERNMENT LABORATORY.

THE report of Dr. T. E. Thorpe, the principal chemist of the Government laboratory, upon the work of the laboratory for the year ending March 31st, 1904, shows an increased activity on the part of this important department of public administration. Originally founded to watch over the interest of the country's revenue departments the work of the Government laboratory now includes a supervision over many commodities supplied to Government departments and provides a means of control over the work of public analysts. The total number of analyses and examinations made in the laboratory in Clement's Inn-passage during the past official year was no less than 85,305. By far the greater number of analyses referred to substances coming under the surveillance of the Revenue department, while some 6000 analyses were made for the Board of Agriculture, the Local Government Board, the India Office, the War Office, and other Government departments. Lastly, 109 samples were referred to the Government laboratory by magistrates under the terms of the Sale of Food and Drugs Acts. There are some curious instances in the report of attempts to evade the payment of duty. Perhaps the most ingenious is in connexion with saccharin which ordinarily bears a very heavy duty. It appears that chemicals have been imported which were so nearly related to saccharin that very simple treatment sufficed to convert them into this compound and it was therefore decided that such substances should be liable to the saccharin duty. Many of the entries or description of goods were found to be incorrect, though in some instances the misdescription was not made apparently with a view to evade the revenue's charges. Certain goods, however, were found to be dutiable, as when ethyl chloride was described as "chinaware," collodion as "lace," spirit as "linen manufactures," and caramel as "perfumery." Imported beers are sometimes described also as extract of malt, though showing the composition and general character of ordinary beer. There has been a considerable increase in the number of samples of cider submitted for analysis for the purpose of ascertaining whether the article as imported is derived from the juice of the apple, in which case it is admitted free, or whether it contains added sugar or extraneous spirit, when it is liable to duty. It is a pity, we think, that the duty cannot be increased on brandy when it contains extraneous spirit. In the Excise department there was also a decided increase of samples examined, due to specimens of beer having been taken from publicans and to an increase in the exportation of medicinal tinctures. Some 1200 samples of beer-wort and materials used by brewers have been tested for the presence of arsenic, and it is satisfactory to learn that the great majority of the samples were found to be either quite free from arsenic or to contain only traces. In regard to so-called temperance drinks, of 852 samples obtained for analysis 269 were found to contain spirit in excess of the legal limit. Some contained 3 per cent., others 4 per cent. and 6 per cent., while the highest contained as much as 9·10 per cent. of spirit. With the sanction of the Treasury the Commissioners have extended the benefits of the Finance Act, 1902, to the medical and science schools of teaching institutions and under special regulation most of these have now been allowed to receive pure alcohol duty free for research purposes. We believe we were amongst the first to call attention to the drawback under which those engaged in research laboured through the prohibitive price of pure alcohol. During the past year the quantity of alcohol actually issued duty free for this purpose was equivalent to 2272 proof gallons. In regard to tobacco, in 248 instances the attention of the manufacturer or dealer was called to the fact that the tobacco contained an excess of moisture and in some instances an excess of oil. Liquorice and glycerine continue to be used for adulterating tobacco. Some flavouring fluids examined were intended for use in manufacturing cigars and were reported against on the ground that it is illegal to use flavouring matter of any kind in the manufacture of cigars. We should like to see a similar restriction applied to tobacco. The analyses made for other Government departments contain some interesting reading. For instance, three samples were examined for the fisheries branch of the Board of Agriculture in connexion with a destruction of fish in a Cumberland trout stream by matter discharged into the river from a paper mill on its banks. The discharge consisted of rosin size and it was found possible to prove the presence of rosin in a scum taken from the river which was stated to be similar in character to a substance found upon the gills of the dead fish. Again, samples of cucumber and of tomatoes were tested for the presence of copper for the Royal Gardens establishment at Kew. With the object of destroying a troublesome parasitic fungus affecting these plants the effect of watering them with dilute solution of copper sulphate had been studied in the gardens and it became desirable to ascertain whether the fruit had in this way acquired any appreciable amount of the metal. Samples grown without the copper treatment were also examined and ultimately it was found that no copper had been taken up by either the cucumber or tomato as a result of the treatment which had been successful in destroying the parasitic growth. The work undertaken by public analysts in connexion with the Sale of Food and Drugs Acts is evidently satisfactorily done on the whole, since of the 104 samples referred to the Government chemists the results differed only in regard to 15 cases. Most of the referred samples consisted of milk. We note with some gratification that the Government chemists have turned their attention to the analysis of brandy in relation especially to its admixture with foreign spirit. In two samples the Government chemists' results confirmed the opinion that the samples did not consist of spirit distilled from wine. This acknowledgment of the value of analysis in differentiating genuine brandy from mixtures of foreign spirit practically decides the question in the affirmative that the sale of brandy can be dealt with under the operations of the Sale of Food and Drugs Acts.

UPPER AIR CURRENTS.

THE existence of upper air currents has been pluckily demonstrated by the Rev. John M. Bacon in a long series of balloon ascents, the results of which he communicated to the recent meeting of the British Association. These upper air currents, he shows, will glide one above another in juxtaposition without commingling and will alter their course and obtrude themselves in a most erratic and unaccountable way where they are least expected. This is a somewhat disturbing circumstance in connexion with the warning sounds given by bells placed on submerged rocks or by foghorns. If the warning sounds emitted by these appliances are dependent upon the caprice of upper air currents it is obvious that they may fail to be heard and thus many lives may be imperilled. Sounds conveyed through the upper air will be carried sometimes to abnormal distances in directions at variance with the ground current, being borne to earth over far but favoured plots of ground while they may pass unheard over districts which might be considered to be well within sound range. An illustration of this was given on the occasion of the booming of guns in the Solent when the body of the late Queen was being conveyed from Osborne to Portsmouth. The sound of the guns firing was distinctly heard at comparatively remote places like Oxford, while at intermediate and much nearer places nothing was heard. Mr. Bacon has also made some experiments with aerial bombs which will presumably account for the occasional suprisingly far travel of sound signals as well as their failure at short ranges. He also allowed a number of light bodies of varying sizes to float away into space at different heights and in different circumstances and these when carefully watched have shown the existence of minor but headlong currents, holding perfectly well-defined courses frequently at variance with that of a balloon. The whole series of investigations is obviously of the utmost importance to the shipping trade and continued research in this direction should, we think, enjoy the liberal patronage of the Admiralty and Board of Trade.

THE TESTING OF CLINICAL THERMOMETERS.

COMPRISED in the scheme of work now carried on at the National Physical Laboratory under the superintendence of Dr. Glazebrook, F.R.S., is the testing of clinical thermometers. Very considerable numbers are sent there for this purpose by makers who, it seems, exhibit a laudable desire to receive the official certificate of verification. In 1901 the tests related to 20,389 clinical thermometers, in 1902 to 22,912, and 19,393 for last year. Since the laboratory was started similar institutions have been founded in France and America, respectively, the Laboratoire d'Essais and the National Bureau of Standards. New buildings for the latter are in course of erection at Washington which are to cost £70,000, while £45,000 are to be expended on equipment, items of provision so liberal that the English establishment suffers severely by comparison. The American Bureau has recently been actively organising the testing of clinical thermometers. A large number of instruments of various types and manufacture were studied for magnitude of errors, aging effects, the nature of the component glass, and other characters. The results pointed to a lack of uniformity in the standards in use by the makers and discrepancy in temperature readings. Consequently the American manufacturers were notified of the erroneous qualities of the thermometers and invited to submit their standards for revision. To this they responded readily, while they have shown consistent interest in the endeavour of the Bureau to introduce a uniform scale of temperature. The methods of testing employed, which are likely to be of service in scientific workshops, will be published shortly. The general nature of the test is a preliminary examination for defects of construction, such as defective graduation, presence of cracks in the glass, air bubbles in the bulb, too great effort to throw back the index below 95° F., and other construction points. No certificate can be allotted where any of these defects are observed at the first stage. Subsequently, for instruments passing these preliminaries, comparison is effected at four different temperatures with the standard thermometers of the American

Bureau in order to determine the magnitude of scale corrections.

SANITARY ADMINISTRATION AT BEXHILL.

WE understand that considerable opposition is being raised at Bexhill to a recent decision of the town council, whereby the appointment of sanitary inspector of the borough will be practically abolished and his duties transferred to the borough surveyor. Considering that the town, which is on the Sussex coast and has a population of about 12,000, is a new and increasing seaside resort within easy reach of London, the wisdom of such a policy seems to be very doubtful. Local authorities are presumably well informed as to local needs, but even though it may be supposed by municipal economists that the sanitary inspector is a "burden on the rates" no health resort can afford to be apathetic in matters of public health administration. An epidemic of enteric fever would be financially an instructive experience in the circumstances. Not only are the great majority of the medical practitioners decidedly opposed to the action of the council but they have signed a petition to the Local Government Board protesting against it and a correspondence published in the *Bexhill-on-Sea Observer* shows that one of the councillors has given notice of a motion for separation of the offices. As there seems to be quite enough work to occupy a sanitary inspector the retention of the separate appointment would apparently be advisable.

PRIMARY TUBERCULOUS ENDOCARDITIS.

AT the meeting of the Société Médicale des Hôpitaux of Paris on July 15th M. Œttinger and M. Braillon communicated an important paper on a subject which has received little attention—primary tuberculous endocarditis. Endocarditis supervening in the course of tuberculosis and due to a secondary infection has been well recognised by French writers since Tessier collected 47 cases in his thesis on "Lésions de l'Endocarde chez les Tuberculeux." This form of endocarditis is usually latent and has only a pathological interest, it does not modify the evolution of the pulmonary tuberculosis, and is due to a secondary infection originating in the pulmonary cavities in which numerous microbes flourish. Nearly every pyogenic microbe has been found in the cardiac vegetations of the phthisical. On the other hand, endocarditis due to the growth in the cardiac valves of the tubercle bacillus appears to be one of the rarest complications of tuberculosis. The lesions may be vegetative or ulcerative. All the recorded cases occurred in pulmonary tuberculosis, generally in its last stage, except one in which the lungs were sound and there was tuberculosis of the spleen. Recently M. Braillon and M. Jousset have reported a unique case of primary tuberculous endocarditis in which the tubercle bacillus was found in the blood during life and in which no other visceral lesion was present.[1] The case ran a subacute course resembling that of malignant endocarditis and proved fatal in three months. In the following case tuberculous endocarditis ran a chronic course, producing a cicatricial lesion of the valves similar to the adhesions which may be left after recovery from tuberculous pleurisy. A woman, aged 23 years, was admitted to hospital on May 20th, 1903. Her father died from tuberculosis. The patient enjoyed good health until July, 1902, when she was admitted to another hospital suffering from feverish symptoms, headache, and digestive troubles. After she had been in hospital some time signs of heart disease were detected. She was discharged in October. Thereafter her health varied and menstruation was irregular and deficient in quantity. On examination the patient was pale and wasted. The apex beat of the heart was in the fifth intercostal space, slightly outside the nipple line. The cardiac dulness extended beyond the right border of the sternum. At the apex a thrill was felt. There were presystolic and systolic mitral murmurs and reduplication of the second sound at the base. The liver extended three or four fingers' breadth below the costal border. The temperature ranged between 101·3° and 102·2° F. There was cough without notable expectoration. At the bases of the lungs there were signs of pleuritic effusion and subcrepitant râles. On the left side puncture yielded only a little blood and on the right sero-fibrinous fluid which presented the cytological characters of inflammatory effusions (polynuclear cells with numerous endothelial cells). On May 25th the temperature was normal. The pulmonary signs at the bases underwent resolution but in the right supraspinous fossa the respiratory murmur was feeble and there was prolonged expiration. The patient remained in hospital until February, 1904, without the cardiac signs changing much. At times there was cardiac failure with dyspnœa, oliguria, congestion of the liver, and irregularity of the pulse. The temperature frequently exceeded 102·2°. Death from cardiac failure occurred on Feb. 10th. The necropsy showed a slightly enlarged heart, adhesions between the two layers of the pericardium, tricuspid and mitral stenosis from old thickening, and sclerosis of the valves. On the auricular side of the mitral valve were small vegetations of the size of the head of a pin. The aortic valves retained their normal suppleness but showed on their cardiac side fine vegetations. Microscopic examination of the valvular lesions showed chronic endocarditis and in places subacute endocarditis but no signs of tuberculosis. Evidently the endocarditis extended back for two years and the aortic lesions were quite recent. There were at the apex of the right lung cicatricial retraction and three small cretaceous tubercles. A fragment of the mitral valve after being broken up and artificially digested (according to the method introduced by M. Jousset) yielded a culture of the bacillus tuberculosis. It is noteworthy that the tuberculous endocarditis ran a chronic course and produced lesions not differing from ordinary valvular lesions. M. Œttinger and M. Braillon admitted that the pulmonary lesion might have been the source of infection but they still thought that the use of the term "primary endocarditis" was allowable. The fact that no evidence of tuberculosis in the valvular lesions could be found by ordinary methods of examination is also noteworthy. However, Peroud and others have shown that in certain cases of pericardial adhesions undoubtedly tuberculous nothing histologically characteristic of tuberculosis may be found at the time of examination.

ILLITERATES AND THE MIDWIVES ACT.

THE recently issued report of the medical officer to the Midwives Act committee of the Lancashire county council fully justifies some of the apprehensions expressed in these columns while the registration of midwives was under debate. We pointed out that under the new law, to be passed for the benefit of parturient women of the humbler classes, the wholly ignorant "Gamp" might acquire a position recognised by law and find her incompetency justified by registration under an Act of Parliament. The midwives who have already been enrolled upon the representation of the Lancashire county council number 418, and among these are 86 women who are "illiterate." The section under which they are placed upon the roll is as follows: "Any woman who within two years from the date of this Act coming into operation claims to be certified under this Act shall be so certified provided she holds a certificate in midwifery from the Royal College of Physicians of Ireland, or from the Obstetrical Society of London, or the Combe Lying-in Hospital and

---

[1] THE LANCET, August 22nd, 1903, p. 551.

Guinness's Dispensary, or the Rotunda Hospital for the Relief of the Poor Lying-in Women of Dublin, or such other certificate as may be approved by the Central Midwives Board, or produces evidence satisfactory to the Board that at the passing of this Act she has been for at least one year in *bonâ-fide* practice as a midwife and that she bears a good character." The phrase "*bonâ-fide* practice as a midwife" is a vague one such as is sometimes introduced into an Act of Parliament and left to be interpreted by those to whom the administration of the Act is confided. It is, however, at least arguable that the women intended are those to some extent *ejusdem generis* with those whose mode of education is specified. If this be admitted it becomes illogical as well as troublesome to frame regulations for midwives and at the same time to enrol women quite incapable of carrying them out. The rules of the Central Midwives Board may, no doubt, be imparted orally to the illiterate but they cannot be obeyed by women unable to write, for they require written reports to be made. Nor are the rules otherwise capable of being understood and carried out by those so stupid and ignorant as not to be able to read in the twentieth century. Compulsory education has now existed for some time, but reading and writing have been for a much longer period within the reach of all endowed with a reasonable amount of intelligence and ambition.

THE VALUE OF EXPLORATION IN SUSPECTED MALIGNANT DISEASE OF THE OVARY.

IT must have happened to all surgeons to meet with cases from time to time where the question as to whether they were justified in recommending operation in what appeared to be instances of undoubted malignant disease has been a very difficult one to determine. It is always a difficult matter to decide to give a patient no chance at all and to condemn to death the subject of an obscure abdominal tumour with the opinion that no operation is justifiable or should be attempted. The question of diagnosis in such cases is so difficult a one and mistakes are so frequently made that the surgeon is always loth to give up all hope and to do nothing. On the other hand, cases of undoubted malignant disease of the ovary, for example, or of the other abdominal organs are often so little benefited by operation and the consequent disappointment to the patient is so severe that the surgeon is disinclined to undertake what he feels cannot but be a hopeless task. In the Ingleby lectures delivered this year Dr. C. J. Cullingworth discusses this very important question and from his large experience of such cases relates some very striking examples of what can be done by modern surgery. His examples are mainly ones of malignant disease of the ovary, a class of tumour of which our knowledge is still far from perfect, and a class of growths therefore in which the exact diagnosis of malignancy must always be a matter of considerable doubt. He brings forward a very strong plea for exploration in such cases and relates some most instructive cases where such growths have been removed with complete success not only immediate but also remote. As he justly points out, what are the criteria, for instance, by which we can say for certain that a papilloma of the ovary is a benign or a malignant tumour? In his opinion at the present time we have no absolute criteria, either clinical or microscopical, by which we can recognise the character of such a growth with certainty. It is often only by the subsequent history of the case that the question can really be decided. Even if the pathologist says, as he often does say, that any given tumour *is malignant*, shall we not if possible remove it in the hope that it may not recur? Undoubtedly, yes; and more especially in the case of many of the more obscure forms of pelvic tumours in which certainty as to their exact nature sometimes cannot be obtained even after they are removed from the body. When the abdomen has been opened and an apparently malignant tumour has been exposed we should try to remove it, at any rate in those cases where it appears possible to do so, in the hope that we may be successful. Even if we do not cure the patient we may prolong life, as several of Dr. Cullingworth's cases show, by many years. And the wisdom of this procedure is seen best of all in the case of ovarian tumours where the border-line between the benign and malignant growths is so ill-defined and obscure.

THE BUYING AND SELLING OF MEDICAL PRACTICES.

AT the recent Lincolnshire assizes, before Mr. Justice Bray, Mr. Douglas Wardleworth recovered a sum of £125 damages for misrepresentation on the sale of a medical practice from Mr. Thomas Cornelius Lawson. The misrepresentations alleged referred to the income derivable from the practice, to the nature of the fees to be expected, to the absence of competition, and to the price paid for the practice, but a feature in the case, which otherwise was not of a nature to call for comment, lay in the fact that Mr. Lawson, who became qualified to practise in 1872, had bought and sold no less than 29 or 30 practices in his professional life! This is a legitimate method of livelihood, no doubt, but at the same time the fact that the vendor is in the habit of so dealing is one which the purchaser would be wise to take into account, if he were aware of it, and a person so selling cannot complain if his representations are scrutinised somewhat unfavourably should any dispute arise with regard to them. Careful inquiry before completing the purchase of a practice will save both parties much anxiety and possible differences afterwards. The intending incomer has a right to the fullest possible information, and, besides inspecting all accounts carefully, he can in most cases make inquiries unobtrusively which will enable him to corroborate or disprove for himself statements as to the class of patients to be expected and as to the presence or absence of competition, with regard to which the vendor may be inclined to take too sanguine a view.

THE RANGOON LYING-IN HOSPITAL.

WE are very glad to see from copies of the *Rangoon Gazette* which have been forwarded to us by Dr. T. F. Pedley that the unfortunate differences which have been crippling the work of the Rangoon Lying-in Hospital have been satisfactorily settled through the good services of Sir Hugh Barnes, Lieutenant-Governor of Burmah. In THE LANCET of Oct. 17th, 1903, p. 1106, we published a short annotation dealing with the unfortunate quarrel which had taken place over the management of this institution. There is no necessity now to recall all the details of the dispute, suffice it to say that owing to the differences of opinion between the official elements and the civil the support given to the hospital had very markedly fallen off and its utility had been much crippled thereby. Moreover, its proper function as a lying-in hospital and a training school for midwives had been abrogated and its usefulness much impaired. Happily, now all the points at issue have been satisfactorily settled, the institution has been restored to its original purpose and the honorary civil medical staff, who had been dismissed by the orders of the late lieutenant-governor, have been reinstated in their positions. A share, too, in the management of the hospital has been restored to the public who, in the first instance, supplied at least half the funds for the rebuilding. There is a very large demand in Burmah for properly trained midwives and in this institution native women are given a complete training and are then able to do something to mitigate the sufferings of their own country-women. The system of dealing with confinement cases prevalent amongst the Burmese and neighbouring people is of the most cruel description and entails an enormous mortality amongst the mothers and children. It will be possible in the new hospital to train annually a considerable number of women and they will be of the greatest assistance as nurses amongst the natives who, unlike many of the Indian races, have none of the caste prejudices and social restrictions which prevent their women from receiving treatment at the hands of physicians of the male sex. Now that all sources of trouble have been removed we have no doubt that the public will come loyally to the support of a most deserving institution and by liberally subscribing to its funds will enable it to carry out the work which it is intended to perform.

THE TREATMENT OF APPENDICITIS.

At the last meeting of the Zürich Society of Medical Practitioners Dr. Theodore Zangger spoke on the subject of the primary treatment of appendicitis. He said that he had always believed it injudicious to let the contents of the colon stagnate, as this hindered the proper drainage of the appendix and offered the most favourable condition for the increase of virulent organisms such as bacterium coli. He advocated the use of small enemata, from half a pint to a pint in bulk and at a temperature between 60° and 70° F., repeated once or twice at the onset and afterwards every two days. Narcotics should be used as little as possible and they could often be dispensed with altogether, especially as the abdominal pain could be greatly relieved by the application of cotton-wool saturated with alcohol of 96 per cent. strength covered with gutta-percha paper and renewed every eight or 12 hours.[1] Of course, cases which began acutely must be referred to a surgeon as soon as possible. Dr. Zangger also quoted the good results which Professor Bourget of Lausanne has obtained by treatment on the same principles.

THE LOCALISATION OF ALKALOIDS IN PLANTS.

An interesting paper was communicated to the meeting of the British Association of Science at Cambridge by Professor L. Errera of Brussels which dealt with the micro-chemical methods by which alkaloids may be located in plants. According to the results it would appear that the qualitative and, to some extent, the quantitative distribution of alkaloids (and especially those belonging to the pyridic series) can be determined micro-chemically in the various organs of the plant with certainty. In living cells the alkaloids are eliminated from the protoplasm and gather in the vacuole, and it is only in cells which have lost all their liquid contents (as in ripe seeds) or in dead cells that they accumulate in the protoplasm or the cell wall. The alkaloids are generally found to be localised. In very active tissues they occur chiefly in the neighbourhood of growing points and in the ovules. In the epidermis the alkaloids are commonly found in the epidermic hairs, and often also in the sub-epidermic layers of vegetative organs as well as in the outer layers of fruits and seeds. In certain of their phloëm elements and in the neighbourhood of the pericycle alkaloids occur encircling the fibro-vascular bundles. They are found also in the phallogen and the youngest cork cells and in laticiferous or similar elements when present. The micro-chemical method has brought to light many more alkaloid-bearing plants, and it is suggested that the application of the method to animal tissue would reveal the existence of organic bases. According to Professor Errera, the results of study seem to show that alkaloids are waste products resulting from the katabolism of cytoplasm and secondarily employed for defence against attack by animals. A few grains of alkaloid constitute a protection not less efficient, he remarks, than the strongest spines.

MUSSEL POISONING.

In another column we publish the report of two cases of poisoning by mussels, one of which proved fatal. Dr. R. Rolfe, medical officer to the New Dock Hospital, Avonmouth, gives an interesting account of the symptoms which were observed and draws attention to the principal features of the cases, the tendency to syncope being one of the most remarkable. It has generally been believed that mussels owe their poisonous properties to incipient putrefaction taking place after the harmless fish were removed from the water or to the presence in them of copper derived from ships' bottoms. Brieger,[1] however, isolated from the poisonous mussels a basic product which he named mytilotoxin. This toxin is apparently formed whilst the fish is still alive and the conditions which lead to its development are water which is contaminated with sewage or other decomposing organic matter or water which is not in free communication with the sea. Dr. Rolfe states that the water from which the mussels were obtained at Avonmouth was known to be polluted by sewage but, nevertheless, the inhabitants of the place often ate shell-fish gathered from this situation. In this instance an attempt had been made to purify the shell-fish by carefully washing them and cooking them thoroughly in several changes of water. The fact that these precautions failed to destroy the toxin is an interesting one and demonstrates the necessity of the greatest care in assuring the purity of the water in the neighbourhood of mussel beds. It has been also shown that if mussels which have thus become poisonous are placed in water in free communication with the sea they rapidly lose their poisonous properties. In some districts mussels can only be obtained at low water; they are then stocked in a pool higher up on the beach. This method would probably tend to favour the production of the toxins, as the shell-fish would be removed from the free and constant contact with fresh sea water; such a practice, therefore, should be forbidden.

CERTIFICATES OF SUCCESSFUL VACCINATION IN SCOTLAND.

The Local Government Board for Scotland in considering the reports made to it by medical officers of health regarding cases of small-pox has had its attention drawn to cases of children (the majority of whom were under five years of age) who presented no evidence whatever of successful vaccination either in the presence of local scars or in modification of the disease, although said by the parents to have been vaccinated. Similar cases have been observed in the course of the inspection of contacts. Further inquiry by the Board has led to the discovery that in many such cases a certificate of successful vaccination had been lodged with the registrar. After investigation of the circumstances under which this occurred the Board has issued an important memorandum in which it states that it "is satisfied that considerable laxity exists in the granting by medical practitioners of such certificates, in respect that they are not always founded on personal inspection of the child after a sufficient interval and occasionally have even been signed at the time of the operation, when its result was unknown and when subsequent inspection would have disclosed failure." A practitioner who grants a certificate of successful vaccination in such circumstances places himself in a very serious position The certificate is to the effect that the operation was performed by the person who signs it and that it has succeeded, and the Board rightly points out that if in either respect the certificate is false the signatory is liable to a criminal prosecution There have already, we are sorry to say, been successful prosecutions in these circumstances, both in England and Scotland, and undoubtedly the medical men in question must be regarded as having committed a serious violation of public duty, properly involving serious punishment The Board therefore has done right to make it publicly known that if in future any case of this nature comes to its knowledge it will be reported to the Crown with a view to proceedings being taken

THE TAMWORTH TOWN COUNCIL AND THE REPORT OF ITS MEDICAL OFFICER OF HEALTH.

WE recently pointed out[1] that the town council of Tamworth (Staffordshire) was greatly at fault in certain notions which it held with respect to the reports of the medical officer of health It appears that "scenes' in the council chamber were attributed to "the action of the medical officer of health in sending his annual report to the Local Government Board and the county council without first intimating to this council his intention to do so" Unfortunately, the council did not at the same time produce any evidence to the effect that it was entitled to have the first inspection of the document in question, and, distressing as it may appear to parochially constituted minds, Dr H J Fausset, the medical officer of health, complied with the statute, even at the risk of ruffling the sensibilities of the council These worthy gentlemen probably now recognise that even their authority has its limitations and have avenged themselves by refusing to pay the bill of £3 18s for printing the report We are glad to see that the *Tamworth Herald* of August 13th contains a letter of protest against this petty and, no doubt, futile attempt at coercion, the writer being Mr A M Sculthorpe, a medical practitioner of many years standing, who has been four times mayor of the town The real cause of the trouble is in all probability the inveterate tendency of some local authorities to consider that the medical officers in their service are dependents requiring to be kept in tutelage by a chairman or clerk to the board Conflicts of this kind are not rare in the annals of local government In 1897, before the creation of the metropolitan boroughs, the vestry of St George's, Southwark, imagined that it could deal with the reports of its medical officer of health as the town council of Tamworth seeks to do The incidents of the controversy, including an appeal to the Local Government Board, were described in THE LANCET at the time[2] and we recommend perusal of the story to the town council of Tamworth

THE medical officer of health of the Cape Colony states that for the week ending July 30th the condition of plague in the Colony was as follows At Port Elizabeth 2 fresh cases were discovered—namely a coloured male on July 24th and another on July 28th Of 90 rats and 234 mice captured or found dead and bacteriologically examined 16 rats and 4 mice were plague infected In the Cape Town and Harbour Board area 520 rodents were examined but none was infected with plague As regards the Mauritius, a telegram from the Acting Governor received at the Colonial Office on August 19th states that for the week ending August 18th there were 5 cases of plague and 3 deaths from the disease As regards Hong Kong a telegram from the Governor received at the Colonial Office on August 22nd states that for the week ending August 20th there were 1 case of plague and 1 death from the disease

IT has been brought to our attention that in our obituary notice of the late Sir John Simon we omitted from the list of that great sanitarian's colleagues the name of John Netten Radcliffe Radcliffe, who was assistant medical officer to the Local Government Board from 1871 until 1883, was one of Simon's most trusted friends and coadjutors His death in 1884 at the comparatively early age of 58 years deprived sanitary science and epidemiology of one of their finest exponents and also lost to this newspaper a valued friend and contributor

THE assistant of the Governor of Odessa, Privy Councillor Stark, M D, died on August 13th, aged 67 years, from paralysis of the heart To him were due, says the *Novoe Vremya*, the successful measures which have protected Odessa and district from Asiatic epidemics

Looking Back.

FROM

THE LANCET, *SATURDAY*, AUGUST 26, 1826.

Much difference of opinion exists, as to the *contagiousness* of *phthisis* This very difference of opinion shews that, at all events, it must be of rare occurrence The exceptions indeed are so numerous as to render it the most probable opinion that the disease is not contagious, and this, I confess, is mine

Causes This disease consisting in inflammation of the lungs it may be brought on by all the causes of inflammation though it often arises imperceptibly, or without being noticed Exposure to cold, injuries of the lungs, irritating matters inhaled in breathing, are among the most frequent It follows also various other diseases, which may be considered to act as *exciting causes*, such are, common inflammation in the lungs, not wholly subdued, neglected catarrh, ulceration, or other cause of irritation about the larynx, any other disease attended with continued *pyrexia* or febrile action, this state appearing to give a disposition to slow inflammation in the lungs, that at length ends in change of structure

Much depends upon *predisposition*, which appears to be induced by a variety of circumstances *Phthisis* is very frequent in cold and variable climates while it is comparatively rare in hot ones It is more frequent between the ages of 15 and 35, than either before or after The *predisposition* is evidently hereditary in many families, and is affected by corporeal figure, the tall and thin, and narrow chested, and the deformed being the most disposed A great number of *phthisical* subjects exhibit marks of *scrofula* in their habit, or have done so at a former period Hence *scrofula* is considered as a *predisposing* cause though we do not know how this acts unless by being attended with a general disposition to inflammation and that of an indolent kind This, in fact, is all we know of scrofula itself[1]

THE TREATMENT OF APPENDICITIS.

AT the last meeting of the Zürich Society of Medical Practitioners Dr. Theodore Zangger spoke on the subject of the primary treatment of appendicitis. He said that he had always believed it injudicious to let the contents of the colon stagnate, as this hindered the proper drainage of the appendix and offered the most favourable condition for the increase of virulent organisms such as bacterium coli. He advocated the use of small enemata, from half a pint to a pint in bulk and at a temperature between 60° and 70° F., repeated once or twice at the onset and afterwards every two days. Narcotics should be used as little as possible and they could often be dispensed with altogether, especially as the abdominal pain could be greatly relieved by the application of cotton-wool saturated with alcohol of 96 per cent. strength covered with gutta-percha paper and renewed every eight or 12 hours.[1] Of course, cases which began acutely must be referred to a surgeon as soon as possible. Dr. Zangger also quoted the good results which Professor Bourget of Lausanne has obtained by treatment on the same principles.

THE LOCALISATION OF ALKALOIDS IN PLANTS.

AN interesting paper was communicated to the meeting of the British Association of Science at Cambridge by Professor L. Errera of Brussels which dealt with the micro-chemical methods by which alkaloids may be located in plants. According to the results it would appear that the qualitative and, to some extent, the quantitative distribution of alkaloids (and especially those belonging to the pyridic series) can be determined micro-chemically in the various organs of the plant with certainty. In living cells the alkaloids are eliminated from the protoplasm and gather in the vacuole, and it is only in cells which have lost all their liquid contents (as in ripe seeds) or in dead cells that they accumulate in the protoplasm or the cell wall. The alkaloids are generally found to be localised. In very active tissues they occur chiefly in the neighbourhood of growing points and in the ovules. In the epidermis the alkaloids are commonly found in the epidermic hairs, and often also in the sub-epidermic layers of vegetative organs as well as in the outer layers of fruits and seeds. In certain of their phloëm elements and in the neighbourhood of the pericycle alkaloids occur encircling the fibro-vascular bundles. They are found also in the phallogen and the youngest cork cells and in laticiferous or similar elements when present. The micro-chemical method has brought to light many more alkaloid-bearing plants, and it is suggested that the application of the method to animal tissue would reveal the existence of organic bases. According to Professor Errera, the results of study seem to show that alkaloids are waste products resulting from the katabolism of cytoplasm and secondarily employed for defence against attack by animals. A few grains of alkaloid constitute a protection not less efficient, he remarks, than the strongest spines.

MUSSEL POISONING.

IN another column we publish the report of two cases of poisoning by mussels, one of which proved fatal. Dr. R. Rolfe, medical officer to the New Dock Hospital, Avonmouth, gives an interesting account of the symptoms which were observed and draws attention to the principal features of the cases, the tendency to syncope being one of the most remarkable. It has generally been believed that mussels owe their poisonous properties to incipient putrefaction taking place after the harmless fish were removed from the water or to the presence in them of copper derived from ships' bottoms. Brieger,[1] however, isolated from the poisonous mussels a basic product which he named mytilotoxin. This toxin is apparently formed whilst the fish is still alive and the conditions which lead to its development are water which is contaminated with sewage or other decomposing organic matter or water which is not in free communication with the sea. Dr. Rolfe states that the water from which the mussels were obtained at Avonmouth was known to be polluted by sewage but, nevertheless, the inhabitants of the place often ate shell-fish gathered from this situation. In this instance an attempt had been made to purify the shell-fish by carefully washing them and cooking them thoroughly in several changes of water. The fact that these precautions failed to destroy the toxin is an interesting one and demonstrates the necessity of the greatest care in assuring the purity of the water in the neighbourhood of mussel beds. It has been also shown that if mussels which have thus become poisonous are placed in water in free communication with the sea they rapidly lose their poisonous properties. In some districts mussels can only be obtained at low water; they are then stocked in a pool higher up on the beach. This method would probably tend to favour the production of the toxins, as the shell-fish would be removed from the free and constant contact with fresh sea water; such a practice, therefore, should be forbidden.

CERTIFICATES OF SUCCESSFUL VACCINATION IN SCOTLAND.

THE Local Government Board for Scotland in considering the reports made to it by medical officers of health regarding cases of small-pox has had its attention drawn to cases of children (the majority of whom were under five years of age) who presented no evidence whatever of successful vaccination either in the presence of local scars or in modification of the disease, although said by the parents to have been vaccinated. Similar cases have been observed in the course of the inspection of contacts. Further inquiry by the Board has led to the discovery that in many such cases a certificate of successful vaccination had been lodged with the registrar. After investigation of the circumstances under which this occurred the Board has issued an important memorandum in which it states that it "is satisfied that considerable laxity exists in the granting by medical practitioners of such certificates, in respect that they are not always founded on personal inspection of the child after a sufficient interval and occasionally have even been signed at the time of the operation, when its result was unknown and when subsequent inspection would have disclosed failure." A and interest than those relating to air space and ventilation. In an Order of 1903 500 cubic feet are prescribed for each person, no height above 14 feet from the ground being taken into account, where certain operations connected with lead (casting, pasting, and lead burning) are carried on in the manufacture of electric accumulators, and 500 cubic feet is also the amount now fixed for the first time as the air space for each person in underground bakehouses. In bakehouses [illegible] is carried on at night by [illegible] ic light, there is to be during [illegible] space for each person. Both [illegible] ouses *are in substitution for* a minimum space of 250 cubic feet formerly permitted, so that the change in so widely practised an industry as baking is one of considerable importance. The new regulations relating to the lead manufactures referred to are in substitution for those made under a certificate that the manufacture of electric accumulators was a dangerous trade and comprise rules as to the other matters which have to be provided for in a lead industry. They came into force on Jan. 1st, 1904.

---

[1] THE LANCET, Jan. 28th, 1899, p. 222.

[1] Ueber Ptomaine, Dritter Theil, 1886.

The question of ventilation is one of importance in all industries, as well as in those in which the nature of the work calls special attention to it. It involves more than the provision of air space and requires more than the goodwill of manufacturers for its solution, and it is one in which the workers themselves are not always on the side of innovation and improvement. The necessity for fresh air is not patent to every intelligence and the cruder method of opening windows and so putting workers in a draught, which is the only means of ventilating familiar to many minds, is reasonably unpopular with persons carrying on sedentary occupations, either in a very high temperature or in unwarmed rooms, in cold weather. With regard to the question of warmth occupiers are instructed to aim at a temperature *not below 60° F. and factory inspectors have* been recently reminded that a reasonable temperature is to be maintained in factories and workshops, "but the measures so taken must not interfere with the purity of the air of any room in which any person is employed."

[illegible] ome of the lady [illegible] difficulty. Miss [illegible] vailing in small dressmaking and tailoring workshops and goes on to speak of a large tobacco factory in which things were no better. She says: "The various processes were carried on in flats round a central well which ran from the ground floor to the top of the building and was devoid of any maintained ventilation. It was quite striking how the impurity of the air increased as one ascended and the accumulated foulness at the top had its comment in the pale faces of the workers there." Miss Sadler reports at length upon the tailoring shops in Cornwall and mentions insufficient means of ventilation as their chief defect. She says: "Most of my visits were paid in April, when the weather was still far from warm, and this lack of ventilation was therefore more noticeable than at a later season. I can honestly record, however, that visits amongst the tailoring slums of Soho and the East-end of London have failed to leave one with such a bad impression. ...... I found in nearly every case the men and women herded together in the workrooms, the men sitting tailor fashion on the floor and the women near them. Of ventilation there was none, unless the small amount of fresh air which might filter through the chinks of the doors or the badly fashioned windows might be dignified with the title of such. ...... Long talks with the employers gave little result. The invariable answer was that the women and men never complained. As a matter of fact, the men often complained to me in private: the women did not, but their pale, anæmic looks were more truthful than pages of spoken or written complaints. Numerous notices to, and correspondence with, the local authorities concerned has perhaps done some good, but it was difficult to impress upon them the fact that the provision of one or two windows cannot be considered sufficient means of ventilation, taking into consideration the fact that those windows have to be closed in cold weather on account of the draught." A London inspector, Miss Vines, writes of the absence of all ventilation in basement workrooms and of one of these where the foreman kept a bottle of lavender salts and burned brown paper to aid in the recovery of the girl *workers who were constantly fainting. Adequate ventila*tion is not likely to be an improvement in the conditions of factory life until the workpeople themselves demand it after having been sufficiently educated in domestic hygiene to desire it in their own homes. Reports, however, speak of increasing intelligence in this as in other matters, particularly where gas stoves and similar methods adopted for raising the temperature at the same time vitiate the air; of these the workpeople complain readily. Reference is made by the lady inspectors and elsewhere in the report to the improvements being gradually introduced in the matter of separate and sanitary closet accommodation for the two sexes. This is regulated by an Order which came into force in July, 1903, and where *it is not in force instances of unsuitable or insufficient* accommodation can be referred to the district council. A state of affairs therefore which in many factories and workshops in town and country alike has been disgusting, indecent, and prejudicial to health is becoming better, the amelioration being welcomed by workers of both sexes. With reference to the attitude of local authorities in sanitary matters the inspectors of the various districts in England give satisfactory accounts of the assistance and coöperation supplied by them and in Scotland and Ireland there appears to be improvement. As to sanitation generally as well as in the provision of sanitary conveniences where large numbers of persons of both sexes are employed, industries of a temporary nature, such as fish-curing, where there is pressure of work at certain seasons and where permanent buildings are not used, seem to present the greatest difficulties. The curing houses at Hull, where the industry is largely practised, appear to be well looked after by the city council and to leave little or nothing to be desired. Great Yarmouth has been very bad in this connexion but seems to be improving.

Writing of South Wales an inspector, Mr. Wolfe, says: "Outside the two county boroughs and, say, two other *districts, sanitation (in factories) appears to me to be as* much a matter of chance as anything else." Of North Wales Mr. Hilditch says: "Much has been done during the year in the matter of sanitary accommodation at factories and the conveniences are approaching something like the prescribed standard. Still there remain a considerable number of places much below it."

Mr. Vaughan reports of North London a continued tendency to move factories to the suburbs where rents and rates are lower and the district generally is less congested. Reference is made to this movement in other reports, Mr. Hoare stating that in East London decentralisation has almost ceased. It is an interesting development where it makes progress, but a note supplied by one of the lady inspectors, Miss Vines, causes a little doubt whether it will obtain enthusiastic support from all classes of workers. Having spoken of the tendency to remove from central London to the suburbs she continues: "With reference to this matter it is curious to note how frequently London born girls are quite unable to accustom themselves to the absence of the rush and whirl of city life. Some time since a large factory was removed to an outer suburb of North London and those of the employés who lived in the city vacated their city homes and came, as the management hoped would be the case, to live in the neighbourhood of the factory. On inspecting the factory this year, however, I was informed that those women and girls who had with the factory removed from the city had been unable to stand the comparative quietness of the district. It was too dull, they said. They had therefore returned to central London to live and came out by train every day to work in the factory." In other words, it is among the women and girls who especially should be benefited by removal into healthier surroundings that least gratitude for the improvement of their lot is likely to be found. They will be ready to put up with the overcrowding and all the other evils which go to make the "housing problem" urgent rather than to give up the cheap music hall and other excitements of city life. With them the "garden city" is by no means likely to find favour.

THE WAR AND THE SUPPLY OF MEDICAL MEN FOR CIVILIANS.—Every day, says the *Novoe Vremya*, the war is thinning the ranks of the St. Petersburg medical men and thus the remaining contingent of town medical men is overloaded with work. Measures are being taken for recruiting a temporary staff to continue on duty during the absence of the city medical practitioners.

ANNUAL REPORT (FOR 1902) OF THE REGISTRAR-GENERAL.

THE close of a Parliamentary session is usually the signal for the issue of a batch of overdue departmental reports in order, we presume, to insure their delivery to Members before the prorogation. Among the Blue-books presented to both Houses on Monday, August 15th, is the Registrar-General's report on the vital statistics of England and Wales for the year 1902.

In reviewing Mr. W. C. Dunbar's first contribution to what we described as virtually a new series of the reports for which he as Registrar-General is responsible, we ventured, on behalf of our profession, to augur a favourable reception for the improvements as regards arrangement which at the dawn of a new century had been introduced in the national records of birth and mortality. A careful examination of the report now before us considerably strengthens the impression left on our minds by the perusal of its predecessor. On reading that portion of the preface to the present volume which bears his signature we notice that the Registrar-General has continued to devote to the details of registration a degree of personal interest which, in recent years at any rate, has not invariably been apparent. Whether it be that nowadays social questions involving considerations of public health have come to absorb more profoundly than of yore the attention of State departments we know not, but there is a passage in the recently issued report of the Committee on Physical Degeneration which indicates that even in their present form the statistical reports of the Registrar-General are appreciated, whilst it conveys the further impression that if the information which they contain were supplemented in the manner and to the extent desired by the committee their value for State purposes would be vastly increased. But the time has at length arrived when the vital history of thirty-three millions of Englishmen, the circumstances attending the life and death of half a million annually of our fellow men, has become a question not of medical interest only but of grave national concern.

We observe that these annual reports are formally addressed to Mr. Walter H. Long who is the Minister accountable to Parliament for the conduct of that office and who also controls the operations of the Poor-law department of the Local Government Board. We further note that in its recent report to Parliament the committee just referred to appeals to the President of that Board to establish and to maintain from henceforth a State register of pauper sickness, the absence of which, as a means of estimating the health of that stratum of the community which is most prone to physical deterioration, the committee greatly deplores. "Of great value," says the committee, "are the Registrar-General's statistics concerning the mortality of the whole population without distinction of social status; but for the reason that no particulars are given on the latter point these statistics are of little value in the present connexion. And yet, as regards sickness that is not necessarily fatal, it appears that for years past there has practically run to waste in this country an enormous mass of information which, had it been arranged and analysed on suitable lines, would have been simply invaluable to the committee at the present juncture. ...... The committee therefore strongly recommends that the assistance of the Local Government Board should be forthwith obtained, with a view of setting on foot and maintaining from year to year a register of sickness (not confined to infectious disease) treated by the Poor-law medical service." The committee further thinks that the tabulation and analysis of such sickness might advantageously be intrusted to the General Register Office which possesses a trained staff and other machinery appropriate for the work. Some years ago an attempt was made to establish a local sickness register in Manchester, largely on the initiative of Dr. Arthur Ransome, then of that city. The undertaking was successful for the time, but being a voluntary one the clerical labour involved soon became too heavy for private resources and, unfortunately, the project was ultimately abandoned, merely from lack of funds. But the Privy Council Committee's present suggestion involves the creation of a State organisation complementary to the anthropometrical survey, the establishment of which it also recommends. And in these circumstances we are convinced that great advantage would result from such a measure which would, we think, receive the support of our profession and we further cordially join with the committee in advocating its initiation at an early date. In that event it is to be hoped that the Registrar-General will see his way to include in his report an annual record of sickness as the natural adjunct to his present record of mortality.

Turning to that part of the report which traces the movement of the national birth-rate, we find that although the rate of births has not further fallen since 1901, it still remains at 28·5 per 1000 of the population, which is the lowest rate on record and is considerably below the decennial average. Turning to the marriage-rate, we notice what at first sight promises to be a set-off to the declining birth-rate. The time-honoured mode of stating the rate of marriage is in terms of persons living *at all ages*, and thus computed the marriage-rate in the three periods ending with 1882, 1892, and 1902 were 15·2, 15·5, and 15·9 per 1000 respectively, showing a *progressive increase* in the marriage-rates as ordinarily calculated. But since a large majority of the population are either already married or are below the earliest marriageable ages, it is obvious that the population at all ages is not a satisfactory standard by which to calculate an increase in the rate of marriage. If the rates be calculated on the unmarried and widowed part of the population *at ages above 15 years* the apparent increase here noted will be turned into a decrease; for the rates in the same periods on this basis are 51·5, 49·8, and 48·7 per 1000. Careful investigation of the facts accordingly shows that although the marriage-rate has increased in proportion to the whole population it has decreased in proportion to that section thereof amongst whom marriages take place.

The most satisfactory part of the report is that which affirms for the whole country a still further decline in the mortality which, happily, has for several successive years been steadily decreasing. Thus we find that the death-rate of England and Wales in the year 1902 did not exceed 16·2 per 1000 of the population at all ages—a rate which was lower than that of any other European State, with the exception of Denmark, Norway, and Sweden. Never since the year 1837, when civil registration was established, has the death-rate been so low as this, the nearest approach thereto having been in 1894 when the rate was 16·6. The greatest saving of lives occurred among children under five years old, at which age the 1902 rates were the lowest hitherto experienced in England both among boys and girls. Reference to the tables and the accompanying remarks, in which are set forth the facts and causes of mortality among the young, indicates that there still prevails in the town districts of England a disproportionate waste of child life. Even in the favourable year under review there was at this critical age an excess of more than 40 per cent. in the town rate of mortality as compared with the country. The tables show that this difference is not due to any one disease or group of diseases in particular, but that the child mortality in towns is above that in the country from every one of the nine tabulated causes. Passing on to consider the causes of death at other ages, the report tells us that from most of the prevalent diseases there has been less than the normal loss of life in 1902. Tuberculosis, for example, which is responsible for nearly 11 per cent. of the mortality from all causes, was fatal in 7356 fewer instances than the average. Among tuberculous diseases pulmonary phthisis is the most destructive, but the death-rate from this disease among males was below the average by 84 per 1,000,000 and among females by not less than 96 per 1,000,000 of the respective populations. There has been in 1902 a considerable decrease in the fatality of tuberculous affections of the brain and its membranes, the mortality from which is practically limited to infants and very young children, not fewer than 68 per cent. of the total deaths being those of infants under the age of five years.

Tuberculous peritonitis is another affection due to the same parasite which is mainly fatal at the earlier ages. The mortality from this disease also was much lighter in 1902 than the corrected average. It is because of the ambiguity attaching to the term *tabes mesenterica*, which unfortunately is still sometimes used as a synonym for tuberculous peritonitis, that difficulty arises in estimating the actual saving of life due to reduction of mortality from diseases of the tuberculous class Among the other more important diseases dealt with in the report there are two only that showed abnormally high fatality in the year 1902, these were cancer and diabetes mellitus The recorded death rate from the disease last named has been steadily increasing for many years past, but it is probable that some of this increase is apparent only and is due to improved medical diagnosis According to the returns the mortality from diabetes mellitus is greater in extra metropolitan England than in London and is increasing much faster among women than among men

In view of the increased scientific interest now taken in regard to cancer prevalence the statistics of mortality from this disease are properly very complete although the corresponding data with respect to its incidence are still sadly lacking The tables before us show that in proportion to population the fatal cases of malignant disease are now more numerous than formerly Nevertheless, some consolation may be derived from the fact that although the death rate has continued to increase year by year the rate of increase was less in 1902 than in the year immediately preceding, notwithstanding the more precise classification now in vogue In view of this encouraging fact the Registrar General remarks "The nature and origin of this disease being now the subject of careful investigation under Royal patronage it is permissible to hope that the cause of this distressing malady will ere long be discovered and that thus its further ravages may at least be controlled" Until quite recently cancer was believed to be more prevalent in the rural districts than in the urban, this opinion being based on examination of crude rates of mortality—that is to say, the rates uncorrected for age differences in the population But when the necessary correction has been made the opposite conclusion follows, this is shown in the present tables, from which it may be gathered that the country rates are much lower than those of the town There is, however little doubt that our great towns are unfairly handicapped in this respect on account of the presence therein of large hospitals and other establishments to which country patients resort for the operative treatment of cancer Inasmuch, however, as no correction has hitherto been attempted for this complication too much reliance should not be placed on the figures contrasting urban with rural mortality from this disease

THE REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1902.[1]

THE volume containing the report of the Sanitary Commissioner with the Government of India for 1902 is somewhat reduced in bulk as compared with its predecessors but it embodies the same subjects and travels over the same ground The fact that these reports deal with the events making up for the most part the medical and sanitary history of India as a whole necessarily entails considerable delay in publication, during which the official returns and data have to be collected, arranged analysed, and commented upon all of which, it is needless to say, give rise to a good deal of laborious work It is not so surprising therefore as it may seem at
figures relating
to 1902
nd of 1903 and
should
ef and
e year
India

The health of British troops serving in India in 1902 with an average strength of 60 540 compares in one respect unfavourably with the previous year in that the death rate (14 68) was higher The chief causes of admission into hospital were venereal diseases and ague which accounted for 26 per cent and 23 per cent respectively of the total number of admissions from all causes Venereal diseases and enteric fever gave rise to increased admission rates as compared with 1901 The chief causes of death in 1902 were, as in 1901, enteric fever and abscess of the liver Enteric fever accounted for 29 per cent and abscess of the liver for 13 per cent of the total number of deaths Among the troops comprising the Delhi manœuvres and Durbar force the chief cause of death was, we learn, enteric fever, accounting as it did for 56 per cent of the total number of deaths among the troops of this force It is a deplorable fact that, despite what bacteriological science has done in giving more precision to our investigations, and despite all the efforts made to search out and remove the causes of enteric fever, so little has been really accomplished in lessening the prevalence of that disease in India While the frequency of epidemics and the losses from cholera among British troops in India have been decreasing for many years past we have failed to make much, if any, impression upon the prevalence and amount of enteric fever in that country

As regards commands and stations, Bombay was the most unhealthy of the four commands, Bengal coming next Among stations of over 100 strength the highest death rates were recorded at Barrackpore, Murree Kakool, Naini Tal, Attock and Fatehgarh Abscess of the liver was the chief factor in the mortality at Barrackpore and Naini Tal, and enteric fever at Kakool Among stations of over 1000 strength the highest death rates were recorded at Colaba and Kurrachee enteric fever being the chief cause at the former station There were only three cases of cholera admitted among the European troops during 1902, as compared with 12 cases in 1901 and 107 cases in 1900 In nearly all stations where a decrease occurred in the admission rate for ague in 1902 as compared with 1901 the decrease was not unnaturally attributed wholly or partially to the measures taken to prevent the breeding of anopheles mosquitoes The decrease in the admission-rate for malaria at Mian Mir was far greater than at any other cantonment in India and the measures undertaken there in anti malarial operations, which were very skilfully devised and superintended by medical experts are well set forth in the Sanitary Commissioner's report (*vide* Section IX pp 103–07) and are also described by Dr J W W Stephens in a paper published in THE LANCET of March 5th, p 637 The difficulties to be grappled with in India are immense and will probably appear insuperable to those acquainted with that country Mian Mir cantonment, it will be remembered, had been examined by the Royal Society's malaria commissioners in 1901 and operations based upon their recommendations were vigorously carried out in 1902 The Sanitary Commissioner with the Government of India considers that on the whole the results of the experiment are against the employment of anti mosquito measures as a practical means of combating malaria in such cantonments as Mian Mir As regards the administration of quinine to the troops, however he thinks that the experiments clearly showed that 15 grains of quinine on two successive days weekly was a powerful means of combating malaria There were eight admissions and one death from Malta fever returned in 1902 as compared with five admissions and no death in 1901, but *the Sanitary Commissioner* is sceptical as to the existence of this form of fever in India and as to the value of the serum reaction as a means of diagnosing it No serious attempt has, he says apparently been made in India to isolate the micrococcus Melitensis and the proof of the existence of this disease in India rests solely on the results of reactions obtained between cultures of the micrococcus and the serum of patients suffering from fever

The report deals very carefully with enteric fever, its etiology and causes pathology and varieties 17 pages being devoted to the subject and to passing in review and epitomising the additions real and alleged, that have been made to our knowledge in these respects as represented in the latest contributions to the literature of enteric fever A list of the numerous papers and books consulted and referred to is given at p 30 *et seq* It presents as usual a very useful and interesting part of the report but we have said so much upon the subject on previous occasions that there is no need to dwell upon it now

Section III deals with the native army of India and gives interesting and valuable information regarding the nature of the fevers *affecting native troops and prisoners* as compared with European troops It is well known that whereas statistical evidence shows clearly a very high death-rate from enteric fever among European soldiers in India it shows a very low one indeed from this fever in the native army and jail population of India. The fever statistics do not reflect, says the Sanitary Commissioner, the opinion so prominent of late that enteric fever is quite common among *adult* natives of India. Lest it should be thought that enteric fever when it occurs among natives is not correctly diagnosed, but is returned under some other heading, the Sanitary Commissioner significantly adds that whether we take the case of native troops or prisoners their mortality from all fevers is considerably below that of European troops from enteric fever alone.

Printing India, 1903 Pp 115 + xx + 125. Price Rs. 3, or 4s 6d.

Passing on to Section IX. of the report there is some interesting and instructive information to be found under the heading of "General Remarks." From a health point of view, as well as from a political and spectacular aspect, the Coronation Durbar at Delhi was, as we know, a remarkable success and the brief reference thereto at p. 102 is worth reading. We have already referred to the subject of malaria in connexion with the experiments which were commenced at Mian Mir in 1902, and which have been carried on up to the date of the publication of this report. An excellent *résumé* of the literature of trypanosomiasis to be found, beginning at p. 108 of this section, to which we may call attention, and at p. 112 there is an interesting account of the discovery by Major W. B. Leishman, R.A.M.C., of an important parasite, together with its history and the work that has been done in connexion therewith.

INTERNATIONAL CONGRESS OF OTOLOGY.

THE seventh International Congress of Otology was held at Bordeaux from August 1st to 4th, the President being Dr. MOURE.

At the opening meeting the PRESIDENT delivered an address upon the History of Otology in France, commencing with the work of Duverney in 1683.

The Choice of a Simple and Practical Acoumetric Formula.

A joint report upon this subject was presented by Dr. POLITZER (Vienna), Dr. DELSAUX, and Dr. GRADENIGO (Turin), who form a permanent committee meeting once a year for studying the points still undecided. Dr. QUIX (Utrecht), Dr. PANSE (Dresden), Dr. TRÉTRÔP (Antwerp), and Dr. BONNIER (Paris) read papers on the same question.

The Diagnosis and Treatment of Suppuration of the Labyrinth.

Dr. BRIEGER (Breslau) said that the radical mastoid operation might lead to the spontaneous cure of a suppurating labyrinth, or, on the other hand, the suppuration, latent before, might become active after the operation and provoke fatal meningitis. He gave the indications, according to the present state of knowledge, for operation on the labyrinth and described the methods of procedure.

Dr. VON STEIN (Moscow) said that he distinguished cases according as the bony capsule, the perilymphatic space, the endolymphatic system, or the whole of the organ was affected.

Dr. J. DUNDAS GRANT (London) spoke of the relations of labyrinthitis to meningitis and to cerebellar abscess. He also discussed the symptoms and compared them with those of cerebellar abscess, with which it was possible also that a labyrinthine suppuration might co-exist.

Dr. POLITZER showed some preparations of morbid changes in the labyrinth in connexion with chronic suppurative otitis media.—Dr. PANSE, the PRESIDENT, and Dr. ESCAT (Toulouse) also made communications upon the subject.

The Technique of the Opening and After-treatment of Otogenous Cerebral Abscess.

Dr. KNAPP (New York) showed an instrument designed by Dr. Whiting (New York) for examining the walls of the abscess cavity. In the after-treatment the most serious troubles were hernia cerebri (which was caused by a secondary abscess) and secondary abscesses inside the cranium.

Dr. SCHMIEGELOW (Copenhagen) advised that the operation should be planned so as to make it possible to explore both the cerebrum and the cerebellum. The anæsthetic should be given with great caution owing to the risk of failure of respiration.

Dr. BOTEY (Barcelona) said that the operation ought always to be commenced by an exploration of the mastoid and the tympanum, passing thence to the intracranial cavity. He advised that in nearly all cases the brain should be punctured through the intact dura mater before incising the latter, in order to make certain of the existence of an abscess, for when the dura mater had been opened by a knife the brain and meninges were much more exposed to infection. He condemned irrigation of the abscess cavity and advised drainage by means of several small tubes.

Dr. GRADENIGO described a special form of intracranial complication with the following association of symptoms—acute otitis media, severe pain in the corresponding side of the head, especially in the temporo-parietal region, and later paralysis of the external rectus on the same side.

Sir WILLIAM MACEWEN (Glasgow) said that he treated the aural and cerebral foci and excised the morbid track between them; neglect of the latter precaution was a frequent cause of recurrences. He preferred chloroform as an anæsthetic rather than ether because the latter induced œdema of the brain. If after having incised the dura mater no adhesions were found in the subarachnoid space he waited 24 hours before incising the brain. After as free an incision as possible he irrigated with the greatest gentleness and used either no drain or at the most sometimes a strand of gauze.

Numerous other communications were made by various speakers, among whom Dr. BROECKAERT (Ghent) showed an ingenious syringe for injecting paraffin while cold; Dr. DENCH (New York) contributed a paper on the Radical Mastoid Operation; and Dr. GRADENIGO and Dr. POLITZER urged the necessity of making the study of otology a compulsory subject.

A small museum of pathological specimens, models, and instruments was arranged in one of the rooms at the School of Medicine where the Congress was held.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

The Borough of Preston.—The history of the isolation of small-pox in this borough during 1903 affords an instructive example of the risks which attend the use of "temporary" hospitals. In 1888–89 a temporary building was erected to cope with an epidemic of small-pox. It was afterwards taken down and stored away until 1893, when it was rebuilt upon its present site and again used in 1903. On Feb. 27th there occurred a gale which completely demolished the eastern wing which, by a happy circumstance, was unoccupied at the time. The remainder of the building was subsequently rendered more secure by props and other supports. There are other instances on record of disasters such as these, and we have heard of children suffering from diphtheria having to be taken from the hospital during a violent snowstorm and placed under a hedge until assistance could be secured. There can be no doubt that although these temporary structures have their advantages their ready destructibility by fire or storm renders them very unsuitable for the isolation of patients acutely ill or otherwise incapable of speedy removal. Two female health visitors were appointed at the beginning of 1903 and they have already done good work in dealing with the excessive infantile mortality for which Preston bears an unenviable notoriety. Mr. H. O. Pilkington, the medical officer of health, mentions the cases of mothers who have had 15, 12, 10, 9, 8, 6, and 5 children, and who have buried 8, 7, 5, 7, 7, 4, and 5 of their offspring under the age of 12 months. The reports of the female health visitors suggest that had the conditions of feeding and nursing of these children been better several of their lives might have been spared.

The Borough of Eastbourne.—The question of providing accommodation at the isolation hospital for cases of pulmonary tuberculosis was considered by the council of this borough during 1903, but after full consideration Dr. W. G. Willoughby, the medical officer of health, arrived at the conclusion that such a course would be undesirable. Dr. Willoughby thinks that it is not the proper function of a sanitary authority "to set up a second infirmary for the chronic and practically hopeless cases that now find their way into the union infirmary" Such cases should, he thinks, be dealt with by the guardi

does not seem to be a suitab

for the purpose of treating

Willoughby thinks that even

the presence of consumptive patients might from a sentimental standpoint injure the present popularity of the institution The other objection which he raises seems to us to have even greater force—i e, that the consumptive patients would have a prejudice against the hospital from the fact that the acute exanthemata are treated there

Plympton St Mary Rural District—Mr S Noy Scott speaks appreciatively of the work of the Didworthy Sanatorium for Consumption which has recently been opened near Brent for the consumptive poor of Devonshire He does not, however, speak enthusiastically as to the results of sanatoriums generally As he observes, it is impossible to segregate into these institutions even a small proportion of the large number of persons who are suffering from pulmonary tuberculosis and it seems, he thinks, "almost foolish to expect that the isolation and treatment of a few of these people for a few months will produce any marked effect upon the prevalence of the disease or reduce the death rate in any way proportionate to the cost which such treatment involves" He sees, too, great difficulty in continuing to provide the discharged patient with anything approaching the abundant food which has formed such an essential part of the sanatorium treatment

The Borough of Torquay—A very useful and encouraging

ries, cowsheds, and milkshops in

by the late Mr P Q Karkeek,

health, and is continued by Dr Thomas Dunlop, his successor Twice yearly a systematic inspection is made, not only of the dairies and cowsheds in the borough, but also of all the dairy farms outside the borough limits which send their milk into the borough As an outcome of these inspections a register is compiled which is printed in the form of a bill and posted up throughout the town, copies being forwarded to all the dairymen and farmers concerned These bills, which may be regarded as a species of informal licence, are in force for six months, when another inspection takes place The farmers apparently welcome the inspections and endeavour to carry out the suggestions made, and a very material improvement in the former condition of affairs appears to have taken place But Dr Dunlop thinks that sufficient care is not taken in the milking of the cows and he states that when some of the milk is treated in a separator the sediment betrays signs of material of which the healthy udder is innocent Proper means for washing the hands of the milkers are rarely seen and the milkers do not wear overalls This is not satisfactory and we should like to see the facts stated on the bill The cow s udders and the milker's hands should be washed before the operation, the milk should be strained immediately after milking, and it should then be cooled All the utensils should be subsequently scalded or preferably steamed The Torquay methods are admirable so far as they go but we cannot help thinking that the informal licences in vogue may prove somewhat a false security if, that is to say, the bills which are posted are intended to imply freedom from the likelihood of specific contamination We hope that Dr Dunlop will continue to deal with this very important subject in his *future annual reports and that he will record annually the* further progress which he has been able to make The Torquay example might be usefully followed in other places

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8896 births and 6639 deaths were registered during the week ending August 20th The annual rate of mortality in these towns, which had been 16·4, 19 8, and 22 1 per 1000 in the three preceding weeks, further rose last week to 22 7 per 1000. In London the death rate was 21 6 per 1000, while it averaged 23·2 in the 75 other large towns The lowest death rates in these towns were 7·8 in King's Norton, 9 6 in Handsworth (Staffs), 10 5 in West Hartlepool, 10 7 in Blackburn, 11·8 in Hastings and in Devonport, 12 0 in Burton-on-Trent, and 12·1 in Bournemouth; while the highest rates were 31 0 in Hanley, 31·4 in Tynemouth, 31·8 in St. Helens, 32 1 in Salford, 32 3 in Tottenham, 33 4 in York, 34 0 in Wigan, 34 6 in Bootle, and 39·1 in Liverpool The 6639 deaths in these towns last week included 2842 which were referred *to the principal infectious diseases*, against 1255, 2059, and 2710 in the three preceding weeks, of these 2842 deaths, 2538 resulted from diarrhœa, 130 from measles, 79 from whooping cough, 39 from diphtheria, 30 from "fever" (principally enteric), and 26 from scarlet fever, but not any from small-pox The lowest death-rates last week from these principal infectious diseases were recorded in Hastings, Bournemouth, Devonport, Burton on-Trent, King's Norton, Stockton on-Tees, West Hartlepool, and South Shields, and the highest rates in Tottenham, East Ham, Grimsby, Birkenhead, Liverpool, Bootle, York, Hull, and Rhondda The greatest proportional mortality from measles occurred in Blackburn, Huddersfield, Halifax, Bradford, and Rhondda, and from diarrhœa in Tottenham, West Ham, East Ham, Leyton, Reading, Grimsby, Liverpool, Bootle, Wigan, York, and Hull The mortality from each of the other principal infectious diseases showed no marked excess in any of the large towns; and no fatal case of small pox was recorded either in London or in any of the 75 large provincial towns The number of small pox patients under treatment in the Metropolitan Asylums hospitals, which had been 46, 32, and 21 at the end of the three preceding weeks, had further declined to 18 at the end of last week, two new cases were admitted during the week, against seven, two, and none in the three preceding weeks The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday *last, August 20th, was 1745, against 1784, 1758, and 1763* on the three preceding Saturdays; 198 new cases were admitted during the week, against 243, 166, and 189 in the three preceding weeks The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 118, 112, and 121 in the three preceding weeks, declined again last week to 106, and were 14 below the number in the corresponding period of last year. The causes of 39, or 0 6 per cent, of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Bristol, Salford, Bradford, Leeds, Newcastle on Tyne, and in 49 other smaller towns; while the largest proportions of uncertified deaths were registered in Liverpool, St Helens, Manchester, Halifax, South Shields, Gateshead, and Tynemouth.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns, which had been 14 1, 14·6, and 15 7 per 1000 in the three preceding weeks, further rose to 17 1 per 1000 during the week ending August 20th, but was 5·6 per 1000 below the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 7 8 in Leith and 12 3 in Perth, to 20 2 in Greenock, and 21 1 in Paisley. The 567 deaths in these *towns included 66 which were* referred to *diarrhœa*, 16 to whooping cough, seven to measles, four to scarlet fever, and one to diphtheria, but not any to small pox or to "fever" In all, 94 deaths resulted from these principal infectious diseases last week, against 58, 85, and 109 in the three preceding weeks These 94 deaths were equal to an annual rate of 2 8 per 1000, which was 6 9 per 1000 below the *mean rate last week from the same diseases* in the 76 large English towns The fatal cases of diarrhœa, which had been 24, 48, and 63 in the three preceding weeks, declined again last week to 66, of which 44 were registered in Glasgow, five in Aberdeen, five in Leith, four in Edinburgh, four in Dundee, and three in Paisley The deaths from whooping-cough, which had been 26 in each of the two preceding weeks, *decreased to* 16 last week, and included 11 in Glasgow and two in Dundee The fatal cases of measles, which had been seven, five, and six in the three preceding weeks, rose again last week to seven, of which three occurred in Glasgow. The deaths from scarlet fever, which had been two, one, and two in the three preceding weeks, further rose to four last week, and included *two in Edinburgh* *The deaths referred* to diseases of the respiratory organs in these towns, which had been 55, 47, and 39 in the three preceding weeks, rose again last week to 47, but were slightly below the number in the corresponding period of last year. The causes of

22, or nearly 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 17·9, 21·2, and 27·1 per 1000 in the three preceding weeks, declined again to 24·5 per 1000 during the week ending August 20th. During the past four weeks the death-rate has averaged 22·7 per 1000, the rates during the same period being 19·7 in London and 14·2 in Edinburgh. The 178 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 18 from the number in the preceding week and included 43 which were referred to the principal infectious diseases, against 13, 25, and 46 in the three preceding weeks; of these, 33 resulted from diarrhœa, four from measles, three from whooping-cough, two from "fever," and one from diphtheria, but not any from either small-pox or scarlet fever. These 43 deaths were equal to an annual rate of 5·9 per 1000, the death-rates last week from the principal infectious diseases being 8·8 in London and 1·4 in Edinburgh. The 33 fatal cases of diarrhœa corresponded with the number in the preceding week. The deaths from measles, which had been four, three, and five in the three preceding weeks, declined again last week to four. The fatal cases of whooping-cough, which had been four in each of the two preceding weeks, decreased last week to three. The 178 deaths in Dublin last week included 60 among children under one year of age and 27 among persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a decline from the number in the preceding week. Seven inquest cases and four deaths from violence were registered; and 57, or nearly a third, of the deaths occurred in public institutions. The causes of nine, or more than 5 per cent., of the deaths in Dublin last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

The following appointment is notified:—Staff Surgeon C. S. Facey to the *President*, for three months' hospital study.

Royal Army Medical Corps.

Captain J. H. Campbell, D.S.O., has arrived at the Station Hospital, Western Heights, Dover, and Captain S. H. Fairrie has arrived at the Station Hospital, Canterbury, both for duty.

Army Medical Reserve of Officers.

Surgeon-Major W. M. Roocroft to be Surgeon-Lieutenant-Colonel (dated August 2nd, 1904).

Volunteer Corps.

Rifle: 2nd Volunteer Battalion the King's (Shropshire Light Infantry): Surgeon-Captain G. Hollies to be Surgeon-Major (dated August 20th, 1904). 1st Volunteer Battalion the Manchester Regiment: Surgeon-Major W. M. Roocroft to be Surgeon-Lieutenant-Colonel (dated August 20th, 1904).

Deaths in the Services.

Surgeon-Major-General Alfred Malpas Tippetts, A.M.D. (retired), recently at Southsea. He joined the army in 1854, became surgeon in 1864, surgeon-major in 1879, deputy surgeon-general in 1880, and surgeon-general in 1891. He served in the Eastern Campaign, 1854–55, with the 7th Fusiliers, including the affair of Bulganac, battles of Alma and Inkerman, and siege of Sebastopol (medal with three clasps and Turkish medal); served in the Afghan war of 1878–80, and took part in the expeditions into Bazar and Hisarik Valleys (medal). He retired with the rank of surgeon-major-general in 1892. A Distinguished Service Reward of £100 a year falls vacant by the death of Surgeon-General Tippetts.

Inspector-General Dugald M'Ewan, H.P.K., R.N. (retired), on the 22nd inst., at Bedford. He reached the rank of inspector-general in 1887.

The Retirement of Lieutenant-Colonel A. F. S. Clarke, A.M.S.

The retirement of Lieutenant-Colonel A. F. S. Clarke, Army Medical Staff, from the post of surgeon of the Royal Military College, which he vacates on account of his having reached the age limit, is a matter calling for some notice on our part. During the time he has held the appointment he has been devoted to his work and to the interest of the college and all concerned therewith. The post is a difficult and responsible one to fill but Colonel Clarke is an officer of sound judgment with a knowledge of the work he had to do, as well as great kindliness and absolute honesty in the doing of it.

The War in the Far East.

The news from the seat of war—such as there is—is of military and not of a medical nature. Beyond the fact that a fierce conflict is raging round Port Arthur and that the garrison of that strong fortress is being hardly pressed we really know but little of what is actually taking place there at the present time. As regards the progress of the war in Manchuria the heavy rains have for the moment put an end to military operations. The rumour is that there is much inefficiency from sickness among the Russian troops under the command of General Kuropatkin.

HOT WEATHER AND FOOD PRESERVATIVES.

To the Editors of The Lancet.

Sirs,—The wave of exceptionally hot weather that has recently visited this country has been followed by the usual epidemic of infantile diarrhœa and the mortality in all the great centres of population has risen in consequence, Liverpool heading the list with a death-rate of 37·7 per 1000. In the conditions under which multitudes of the poor live it is not a matter for surprise that diarrhœa due to the consumption of decomposing food should be extremely prevalent. Even in the houses of the well-to-do it has been difficult to keep milk, fresh meat, and fresh butter in a condition fit for consumption for more than a few hours and some of it has often had to be thrown away as not above suspicion. In the slum dwellings of our great cities the difficulty of keeping fresh food in a state fit for consumption must be well-nigh insurmountable. The air of the overcrowded rooms reeks with organic emanations from the bodies and clothes of the inhabitants; water has to be fetched from a standpipe outside and is used sparingly; there are no relays of dishes or other receptacles to hold the food, such receptacles as exist are dirty; there is nothing to keep off the flies, and when food goes bad the family must eat it or do without any. These conditions are not peculiar to Liverpool but are met with in all large cities, but there is one circumstance about Liverpool which I think explains, in part at least, their disastrous influence on the health of the children there during the last few weeks. For some years past the authorities in Liverpool have been carrying on a crusade against the use of boric acid and salicylic acid as preservatives in food and I am of opinion that the success of the authorities in putting a stop to the use of preservatives has laid the public open to serious risks from poisoning from decomposing food. Some months ago, when discussing the question of preservatives with an official who was strongly opposed to their use on the ground, as he alleged, that by sterilisation the food could always be delivered to the consumer in good condition, I asked him how it was to be kept from going bad directly it was opened. His answer was that the officials had nothing to do with the food after it had reached the hands of the consumer, that the only business of the officials was to see that the consumer got it pure, which meant in this connexion free from preservatives. This view may satisfy the official mind but it is not sense. I have more than once invited the opponents of the use of preservatives to bring forward a single instance in which any human being has suffered from the reasonable use of boric acid or salicylic acid as preservatives in food, but they have not brought forward a single case that would bear investigation. The objections to their use are purely hypothetical, chiefly resting upon feeding experiments on young animals which have been wrongly interpreted. On the other hand, no one seriously disputes the danger of consuming food even in an early stage of decomposition and I assert without fear of contradiction that in the conditions under which the poor live in our large cities their food is certain to undergo rapid decomposition in hot weather unless preservatives are employed I am, Sirs, yours faithfully,

THE AMALGAMATION OF THE LONDON ORTHOPÆDIC HOSPITALS

To the Editors of THE LANCET.

SIRS,—As one of the governors of the City Orthopædic Hospital by whose vote it was decided to refuse to incorporate with the two other orthopædic hospitals, I think it only right to state our reasons for this refusal and I think that when they have been considered the action of the Hospital Sunday Fund committee in refusing the usual grant to this most deserving institution for the purpose of coercing them will appear most unjustifiable The City Orthopædic Hospital is worked at very small cost for administration and nearly the whole of the money subscribed goes to the patients It is on a freehold site in one of the most accessible spots for the poorer inhabitants of London, it can be reached by a 1*d* omnibus fare or 1*d* railway fare from all the poorer districts of London It treats a class of disease to which the poor are particularly subject
I
the three orthopœdic hos
t immense cost on a lease
[illegible] London, thus taking it too far away from the poor districts and spending a very large sum on bricks and mortar, which is at present available for relieving the very great sufferings of the people The proceeding would increase the administrative expenses much out of proportion to the good to be derived from the amalgamation I think that pressure must have been brought to bear in some way to prevent the usual grant, as I cannot understand anyone who has gone into the matter fairly refusing funds to so deserving a charity as ours I feel sure that it is only necessary for anyone to visit this institution, which is situated in Hatton garden, to see how carefully the committee have husbanded their resources and the very kind way in which the poor little sufferers are treated to insure plenty of donations and subscriptions to carry on this most humane work without the aid of the Hospital Sunday Fund committee I am, Sirs, yours faithfully,

Sydenham, August 18th 1904 JAMES A PHILLIPS

DOES BOILING IMPROVE THE KEEPING PROPERTIES OF MILK?

To the Editors of THE LANCET

SIRS —To most practitioners I apprehend that the boiling of milk at this season of the year for the purpose of "keeping it sweet" is an axiom of practice which I had always suspected admitted of no doubt Recently however a friend of mine, a bacteriologist vigorously attacked my instruction to boil milk 'Why" he asked, "do you boil the milk? I replied first at this season of the year to prevent souring and decomposition, secondly to destroy pathogenic germs, thirdly, it is said to make the milk more digestible, and lastly, if the child has diarrhœa it is to help to constipate the child

Now, does boiling the milk have a good effect on its keeping properties, especially under the contaminating influences of hot weather? I have always thought so, but my friend roundly declares that it is absolutely harmful, and for these reasons First, he says that I confuse souring with decomposition or putrefaction The one is due to lactic acid fermentation, the other to changes set up by dirt organisms or the organism of putrefaction, two altogether different processes and mutually antagonistic When we set about boiling the milk we destroy the lactic acid organisms, which die, say, at or about a temperature of 180°, while the dirt organisms, which are spore bearing, are at that temperature quite unharmed What then, is the result? The milk is certainly, by the act of heating, prevented from souring and to outward appearances keeps good, but if it is kept for a few hours—probably all night—at the temperature of the room or flat, say at or above 80°, putrefaction has full opportunity of taking place under the most advantageous circumstances and toxic agents are developed in the milk which are much more pernicious than the souring Souring is such a visible process that it is unmistakable but, on the other hand, these invisible toxic agents give no evidence of their existence, either in taste or smell (possibly in some instances the milk may become slightly sweeter), by which they can be recognised and these products, my friend declares, are often the deleterious substances which give rise to the fearfully sudden collapse in some infants about whose feeding the mothers have been more than usually careful by taking pains to boil the milk before using it My bacteriological friend goes so far as to say that sour milk in itself is *not* harmful! This statement reminds me that in my native county basins of sour milk were eaten with avidity, mixed with the coarse brown sugar of olden days or with treacle, by the farm hands on many of the farms I have stayed at in the days of my youth He urges strongly that the lactic acid fermentation is actually nature's own means of preventing the process of putrefaction owing to the fact that most of the putrefactive germs require an alkaline or neutral medium for their development and that this is impossible as long as the lactic acid germs are allowed to exert their influence, but directly we set about killing these by boiling we immediately give the putrefactive germs full scope to develop and this by the very means which we in our ignorance of nature's processes had hoped would be effective in the opposite direction

I am, Sirs, yours faithfully,
RICHARD BEVAN, L R C P Lond, D P H
Kensington August 5th 1904

⁂ Boiling must obviously delay decomposition by destroying germs but the effect, of course, can only be temporary if the milk is afterwards allowed to cool down exposed to the air The destruction of pathogenic organisms is more likely to be effectually done by heating than by waiting for the development of lactic acid —ED L

PREVENTION OF PUERPERAL FEVER

To the Editors of THE LANCET

SIRS —The paper written by Professor Byers on this subject leads one to think furiously For years past the members of the medical profession have listened to very tall talk from obstetricians and we are still to listen A little incident occurred at Oxford at a discussion in the obstetrical section upon the treatment of accidental hæmorrhage which I trust will tend to make our obstetrical professors also consider *Professor Galabin informed his* audience that he had been in favour of the treatment of vaginal plugging and was so at that moment, that he advocated this method in early editions of his little book for students but that he had omitted to do so in later editions because he found that his students complained that they failed to pass examinations for stating that this was the method which in practice they would adopt The method in question, I may perhaps be allowed to state is that which was taught by those great authorities Dr Rigby and Dr Matthews Duncan It was strange to find that the reintroduction of the method has been necessary

I shall be glad to hear in what proportion of the reports written by medical officers of health annually is attention called to excessive puerperal mortality If
any accurate apprec
ordinary working acc
some attention must l
obtain in those parts
is high So far as my limited lights allow me to form an opinion the prevalence of puerperal sepsis—or indeed surgical sepsis—depends first upon the sound grounding of students in first principles by the teacher, secondly, upon
nd thirdly, upon the
it when he becomes a
period since Hughes
Bennet introduced the speculum and passing in review the various teaching concerning the so-called congestions and ulcerations of the cervix, concerning the use of pessaries, concerning operative interferences with women for disease not connected with pregnancy, and concerning operative interference with the various complications connected with pregnancy and childbirth, it is impossible to assert that the teachers of the third compulsory branch of professional

said: "I must ask you to be careful and remember that you come here as an expert witness. If a man falls as a result of slipping upon a piece of banana skin, do you, as a medical man, say that indicates a dangerous condition of the brain?" To this inquiry the witness replied: "Taken in connexion with the sprained thumb I think it would." After evidence from Professor R. Saundby, who, whilst refusing to go so far as the last witness, was of opinion that the accidents should have been disclosed, the Lord Chief Justice in summing up said that a policy of insurance depended upon absolute good faith upon both sides. What the jury had to decide was whether the questions had been answered correctly by the deceased. In considering whether the two occurrences in question were accidents they should not pay much attention to the fact that the deceased described them as such to the accident insurance company, since he could not well have described them as anything else. If they thought that the information as to the injured knee and the sprained thumb was the sort of information that the questions submitted on the paper of application were intended to elicit, then they must come to the conclusion that they were incorrectly answered. The jury found that all the questions were correctly answered.

Health of the City.

The epidemic of diarrhœa which visits the city at this time of year has put in its appearance with the hot weather and an abundant fruit-supply. In the week ending July 23rd there were 27 deaths from diarrhœa; in the following week 76, and in the third week 98. This increased the death-rate to 23·3 per 1000. The zymotic death-rate rose in the same time from 8·5 to 10·8.

The Sewage of Hanley.

Dr. George Reid, medical officer of health of Staffordshire, has presented to the sanitary committee of his county council a report on certain experiments in connexion with sewage which have been going on at Hanley for the past two years. Works were constructed for treating one-sixth of the dry-weather flow of the sewage of Hanley on biological lines, the object being to determine by experiments on a large scale whether septic tank treatment followed by single filtration would yield satisfactory results with the sewage in question, and whether the process could be conducted on the site of the present outfall works, which is at no great distance from a populous part of the borough. For many years past, and at the present time, the method of disposal has been by chemical precipitation followed by land treatment. The land available, however, is very ill suited for the purpose and the area is altogether inadequate. It has become clear that the idea of continuing land treatment must be given up if the present outfall is to be retained. Mr. Scott-Moncrieff designed a piece of apparatus for the distribution of the tank effluent upon a circular filter, and Mr. Wilcox designed a mechanical distributor which was fixed in connexion with a rectangular filter. Both of these pieces of apparatus have been at work during the whole time that the experiments have been in progress. The area of the experimental filters amounts to half an acre, one quarter of an acre being given to each shape of filter. In both cases a depth of 4 feet 6 inches of filtering material was used. This material was broken "saggers," a waste material which is to be had in any quantity in North Staffordshire. The filters were divided into sections in each of which the particles were of different sizes and the effluent pipes were so fixed as to allow of samples being separately collected from each section. This was done with a view of ascertaining which size of particle was the best adapted for the purpose. The filters have now been in operation for some 18 months. A constant and regular flow of 200 gallons per superficial yard was obtained from the circular filter. The flow from the rectangular filter was not so large nor so constant. It varied from 130 to 200 gallons, the mean having been 162 gallons. After tabulating the results of the analyses of the sewage and of the effluents in respect of the various filters Dr. Reid proceeds to state that the conclusion to be drawn from the figures is that in every case the degree of purification which has been effected is excellent. The good quality of the work done exceeds that of any plant of which he has had any experience, neither did he know of any published records from similar works which would approach those of Hanley as regarded the degree of purification effected. Treatment in the "septic" tank effected a purification of 64 per cent. and 62 per cent. in the organic ammonia and oxygen absorbed respectively, whilst as regards the filter effluents these percentages varied from 94 per cent. and 91 per cent. in the case of the large grain section of the circular filter to 97 per cent. and 94 per cent. in the case of the finest grain section, the last-named figures being practically the same in the corresponding section of both filters. As regarded the degree of purification effected, the results were practically the same in corresponding sections of both filters. With reference to the routine working of the filters, with the exception of a temporary water-logging of the large grain section of the circular filter (1½ inches to ½ inch fragments), an occurrence which was corrected by a short period of rest, no trouble was experienced. In conclusion, Dr. Reid states that the working of the preliminary plant has exceeded his highest expectations, and he is of opinion that the Hanley corporation might with confidence proceed to lay down, on similar lines, a plant of sufficient capacity to deal with the whole of the sewage of the borough.

August 23rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Prevalence of Diarrhœa and its Causes; Discussion at the Health Committee; High Rate of Mortality.

AT the meeting of the health committee held on August 18th attention was drawn to the prevalence of diarrhœa and the high death-rate of the city for the past two weeks, which had reached 37·7 per 1000. Dr. E. W. Hope pointed out that, in regard to the causes of diarrhœa, it occurred at a certain season—namely, the season of decay, when food became rapidly putrescent. In turn in every town in the civilised world there was at that season an enormous destruction of infant life, but it was almost entirely confined to those whose mothers, from one cause or another, did not suckle the infants. Dr. Hope said that the returns from Birmingham, Aston, York, and other places also showed a high rate of mortality but the causes did not operate in every town at the same time. Many circumstances did not coincide to make the rate uniform every week. Unfortunately, for two weeks Liverpool had been at the top but other places followed closely with 36. 35, 32, &c., per 1000. The high death-rate had happened only for two weeks in Liverpool and he thought it was an encouraging thing that such a rate was so rare that it was seized upon now and made the subject of a great deal of conjecture. He was sorry to see a somewhat wrong impression created. The rate last year and right up to July of this year was about 19 per 1000, taking the whole period. They knew that they could not go on with such a low rate. The birth-rate in Liverpool was much higher than in the majority of places and thus they had a much larger infant and susceptible population. The high death-rate would probably continue for a week or two, possibly to the end of September. There was no royal or magic road to stop the disease. The proper course was to adopt Nature's methods; if her methods were set aside she would have her revenge. The supplying of sterilised milk, which had been copied from France, had given most promising results. Next to mother's milk it was the best food for infants, but the difficulty was that as there were thousands of mothers who could not suckle their children so there were thousands who would not give them sterilised milk. As regards the prevalence of scarlet fever and typhoid fever Liverpool occupied a relatively satisfactory position.

Beri-beri in Liverpool.

A Norwegian barque, the *Sunniva*, arrived in the Mersey on the morning of August 18th, from Cuba, with five cases of beri-beri on board. The patients are Norwegians. The sanitary authorities, taking the matter in hand, had four of the men placed in the tropical diseases ward of the Royal Southern Hospital, which possesses an admirable equipment for observing and dealing with such cases. Two of the men are suffering severely from the disease. Leaving Algoa Bay as early as March the vessel, with the sufferers on board, reached Santa Cruz, Cuba, in May. Thence they set out for the Mersey, which was reached, as stated, on August 18th.

Lancashire County Council; Registration of Midwives; University Grants.

The midwives committee of the Lancashire county council reported that certificates had now been granted to 457 midwives out of 524 who had applied It was recommended that as the regulations were very stringent and so many of the women were illiterate a trained obstetric nurse should be appointed as inspector of midwives at a salary of £104 a year The council has increased its grant of £500 to the University of Liverpool to £1000

August 23rd

IRELAND

(FROM OUR OWN CORRESPONDENTS)

National Veterinary Association

THE members of the National Veterinary Association opened their ust 15th in the lecture theatre where they were received by Mr e President, who welcomed them on behalf of the Royal Dublin Society The President of the association, Mr Clarke Allen, delivered an interesting address in which he alluded to the fact that since they last met in Dublin four years ago Professor Koch had startled the world by stating that tuberculosis of the lower animals was not the same as tuberculosis in man and that the one could not be transmitted to the other The interim report of the commission which was appointed to investigate the question and of which a very distinguished Vice President of their association, Professor D J Cunningham was a member, did not support the view of the great German scientist The members of the veterinary profession had good reason to doubt its truth and were aware of the loss of valued colleagues from tuberculosis with which they were accidentally inoculated while making post mortem examinations

Infantile Mortality in Dublin

At the meeting of the public health committee held on August 16th the death rate for the previous week was reported to be 28 1 per 1000 and of this large mortality no less than five deaths in every thousand were due to diarrhœa Sir Charles Cameron said that he was issuing a circular setting out what precautions should be taken to reduce the mortality from this cause Professor Antony Roche addressed a letter to the papers on August 18th in which he described the method adopted by the Liverpool sanitary authorities in connexion with the matter Depôts were established throughout that city where parents could obtain pure milk for infants supplied in small separate bottles As appeared in the last report of the Liverpool medical officer of health this had the effect of diminishing the infantile death rate from diarrhœa The council of the Dublin Sanitary Association attention to the fact that deaths in this city during the six, five, 15, and 33 respectively, and mentioned the well established fact that when the subsoil temperature at a depth of four feet below the surface reaches 56° F diarrhœic affections become prevalent each summer

Small pox in Dublin

No new cases of small pox have been reported in Dublin and the three patients in the isolation hospital are convalescent All the members of the Royal Irish Constabulary stationed at the Dublin depôt who have not been vaccinated within the last two years are now having that operation performed by order of the authorities

The Belfast Board of Guardians

The proceedings at the last meeting of the Belfast board of guardians tend to bring popular representative government into contempt, the lively discussion general wrangling "disorder' interruptions" 'uproarious scene of excitement' 'uproar and "low personal remarks,' as reported in the daily papers of August 17th being a disgrace to any body of individuals who are supposed to have charge of the poor The whole fa question of a proposed be admitted that a lette in Dublin had the effect outset of the meeting two inspectors of the Local Government Board held a public inquiry some considerable time ago (in December, 1903) in reference to the suitability of a place known as the Abbey in the neighbourhood of Belfast, which the guardians wished to acquire as a consumptive sanatorium These inspectors have already reported and now the Local Government Board writes, after all the correspondence and the inquiry that if the guardians are prepared after full consideration, to place a definite scheme before it and if they are satisfied that the Abbey is the most suitable site for their purposes the Board will be ready to give its decision on learning fully the guardians views Evidently the Local Government Board is unable to make up its mind on the question and wanted to know if the guardians were in the same state, and the discussion which ensued showed that the guardians are so divided in their views The matter was finally referred to the infirmary committee While an immense deal of public time was being wasted in unseemly discussion matters requiring serious attention were being neglected As an example, a report from the works committee revealed a serious state of affairs in the children's infirmary, for Miss Ward, the lady superintendent reported that "the patients in the children's infirmary are infested with vermin, and owing to the walls and woodwork it is impossible to keep the beds free from these pests The beds in use are old and so constructed that insects get into crevices at the joints The members of the works committee not only confirm these statements but say that during their inspection of this department they observed a loose board on the ground floor and on lifting it there was some sewage matter lying beneath it When it is considered that this is the state of an institution over which the guardians who wrangle at length on personal matters are the responsible authorities it is little wonder that some people think that the Local Government Board should dissolve the Belfast board of guardians and appoint two or three paid officials to manage the workhouse

Small pox in the North of Ireland

It is to be regretted that small pox continues to spread throughout Ulster At Monaghan attention was drawn at a meeting of the guardians on August 22nd to the part played by the professional tramp in spreading the disease, especially those coming from places like Armagh and Clones where the epidemic is prevailing If tramps were dealt with as the "work shys are treated in Switzerland the nuisance which is present all over Ireland would gradually cease In Switzerland able bodied vagrants are arrested and sent to a home of correction where they are forced to labour or to a farm where they must keep pace with the voluntary worker There are 21 cases of small pox in Armagh where there is not adequate accommodation in the view of the Local Government Board, which recommends that instead of cases being treated in the fever hospital (which is close to the infirmary) an additional shed should be erected to accommodate, say, 30 patients The fever hospital should be cleared of the small pox cases and thoroughly disinfected and reserved for other forms of fever At present the enteric fever cases are being treated in the infirmary wards reserved for consumptives and there is no accommodation for the "contacts' The Newry guardians on Sept 3rd are to consider how they will arrange to accommodate small pox cases should the disease appear in their area Enniskillen and Omagh are also making preparations

Increase of Dispensary Medical Officers Salaries

The Banbridge board of guardians at its meeting on August 22nd decided to increase the salary of Dr W J Cowden of Dromore from £80 to £110 per annum and that of Dr J Taylor of Tanderagee from £100 to £120 per annum Dr Cowden has had a service of five and Dr Taylor of 25 years

The Belfast Maternity Hospital

The new Belfast Maternity Hospital which will be of so much value to the medical school, is to be opened in November by the Countess Grosvenor, wife of the Chief Secretary for Ireland

August 23rd

PARIS

(FROM OUR OWN CORRESPONDENT)

The New Nursing School

THE first school for sick nurses which is open to all classes, has just been opened in Paris The scheme was initiated by Madame Allegret the head of the École for girls at Versailles and Madame Alphen Salvador The school includes a hospital of 20 beds and as many private rooms In consideration of a fee of 600 francs per annum, payable quarterly in advance and guaranteed by the relatives of the pupils, the school takes such pupils completely under its charge, boards them, lodges them, and gives them full instruction both theoretical and practical. The practical instruction is given daily at the bedside of the patients in the hospital attached to the school and when the pupils are not on duty here they go from nine o'clock till 12 to the various hospitals in Paris so as to familiarise themselves with the nursing of all kinds of diseases. Lectures are given every day from five to six o'clock and include the subjects of anatomy, physiology, general and professional hygiene, minor surgery, massage, general medicine, diseases of children, the nursing of patients suffering from cutaneous diseases, the elements of pharmacy and professional etiquette (*devoirs*). The first year is a year of probation and if the pupil finds the work suits her she undergoes at the end of her first year an examination, after which she begins the second year of her studies and signs an agreement to serve the administration for four years. At the end of the second year she receives her diploma of assistant and from that moment begins the exercise of her profession. The school pays her 1200 francs per annum and this salary increases by 100 francs every three years, that is to say, at each renewal of the agreement. The school pays the salary whether the nurse is at work or not and when a nurse is sent to look after a patient in a private family the conditions of her stay are regulated by the work which she has to do and the administration receives the report of her work but she herself is prohibited from taking any fee. In return for this the school pays all the expenses of the pupils. If a pupil wishes to break her agreement during the three years to which it refers she must pay an indemnity which varies from 250 to 1000 francs. Uniform is a necessity. When attending on a patient the uniform is of pink cotton. When going about a town the uniform consists of a dark blue woollen dress with linen collar and cuffs.

Tobacco and the Sense of Hearing.

At the Congress of Otology at Bordeaux M. Delie read a paper upon Tobacco and the Auditory Sense. Tobacco, he said, exercises a direct and selective action upon the auditory nerve and nicotine brings about circulatory troubles, owing to its exciting action upon the great sympathetic. It also gives rise to, or stimulates, a trophoneurosis which ends in neuritis of the auditory nerve. Tobacco should be used in moderation and practitioners should warn patients in whom there is already auditory trouble that its action is specially harmful in their case. In persons who are already suffering from arterio-sclerosis or who have a family history of such a condition it ought to be forbidden, and all the more if they are comparatively young.

Should a Medical Man Recommend a Pharmaceutical Chemist?

The question has recently come up as to whether a medical man has the right to recommend a particular pharmaceutical chemist to his patients for making up prescriptions. The Tribunal of the Seine has already given judgment on this point and it is as well to recall the judgment now that the matter is being discussed afresh. The court declared that it is the business of the medical man to ascertain that the drugs which he orders are supplied in an active condition. If he knows that any particular pharmaceutical chemist sends out defective medicines he can—nay, should—recommend his patients to go to another pharmacy for their medicine. As this judgment did not please the particular pharmaceutical chemist to whom it referred the Court of Appeal was applied to and this court simply confirmed the judgment of the court below.

The Poison of the Bee.

At the meeting of the Academy of Sciences which was held on July 25th M. Phisalix read a paper giving the results of some researches which he had carried out upon the poison of the bee. He stated that sparrows form very delicate physiological tests for this poison. If a sparrow be stung in the pectoral region by two or three bees symptoms of poisoning supervene in five minutes at the latest. The earliest symptom is general and progressive weakening of motor power, the bird sinking down on its feet; if it tries to fly it almost immediately falls. The paresis gradually increases until all that the bird can do is to flutter along, scraping the ground, it oscillates, and its movements are incoördinate. Then follows a generalised and increasing tremor—in fact, a regular chorea (*danse de Saint Guidans*), in which the muscles of the feet, the head, the wings, and the eyes are all affected. Respiration gradually fails and the bird opens its beak as if gasping for breath. Intelligence is not affected and the bird will defend itself with both beak and claws, but towards the end the chorea is frequently interrupted by periods of somnolence. The paralysis increases and the bird dies in two or three hours from respiratory failure, though the heart goes on beating for some minutes after the respiration stops. Post-mortem examination shows that the blood in the heart is black and coagulates rapidly, while the area of the stings in the pectoral muscles is of a light yellow colour due to commencing mortification. If a solution of the venom be made it can be analysed physiologically and as inoculated by the bee it is found to contain three principles—one convulsive, one stupefying, and one which gives rise to acute inflammation (*phlogogine*). The existence in the poison of an insect of two poisons directly opposed to one another is a newly discovered fact which may be compared with the observations of M. Bouchard upon the poisons of urine.

X Rays and Constipation.

At the congress for the furthering of science which was held at Grenoble from August 4th to 11th M. Albert Weil read a paper upon the results of some observations which he had made as to the application of the x rays upon a limited area of the abdomen. He used as strong an application of the rays as the skin could support without injury and he found that when this treatment was repeated twice or thrice a week it had an action upon the intestines which allayed spasms and produced healthy motions in patients who had hitherto been unaffected by every kind of medication.

Obituary.

Dr. Dureau, the librarian of the Academy of Medicine, Chevalier of the Legion of Honour, died on August 12th, universally regretted.

August 23rd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Serum Treatment of Puerperal Septicæmia.

AT a recent meeting of the Berlin Medical Society Professor Bumm read a paper on the Serum Treatment of Puerperal Septicæmia. He said that there was a difficulty in making a proper estimate of the action of the serum and that recoveries might be attributed to nature as well as to the serum treatment. He has used Marmorek's, Menzer's, and Aronson's serum, the result being as follows. Streptococcic puerperal peritonitis: five cases were treated by injections of great quantities of serum without success. Genuine septicæmia: in two cases the serum had not the least effect, one case in which great masses of streptococci were present in the blood recovered after three injections, while two cases complicated by endocarditis were not influenced. Pyæmia: no effect was produced by the serum. Streptococcic endometritis: of 35 cases five died, nine recovered without a manifest action of the serum, and in 21 the injection produced an immediate decrease of the temperature together with an improvement in the patient's general state. Although the advantages of serum treatment were very doubtful it was at least harmless and Dr. Bumm recommended that it should be tried in severe cases. In recent cases without general infection it should always be used. Prophylactic injections should also be given with a view to prevent cases from becoming septic.

The Waldschule of Charlottenburg.

According to an article published in the *Vossische Zeitung* a so-called "forest-school" (Waldschule) was opened on August 1st by the municipal authorities of Charlottenburg, a suburb of Berlin. This institution is a new departure in school hygiene. It was found long ago by school teachers that a good many children fell behind in the ordinary schools because they were anæmic, badly fed, and neurasthenic, although not suffering from any definite illness. In certain towns, Nauheim, for instance, special classes limited to a comparatively small number of pupils have been formed for such children and in these classes great attention is paid to hygienic measures such as bathing and to the reduction of school hours. Another plan was suggested some years ago by Professor Baginski, the well-known specialist for the diseases of children; he advised the Berlin school authorities to establish "internats" in the neighbourhood of Berlin, where children suffering as above mentioned would live in the country, but his proposal was not adopted as it would have involved an enormous expense. The new system of the Charlottenburg Waldschule differs from that plan as the children and teachers stay there only during the day and return home in the evening, as is the case in the so-called Erholungsstätten for tuberculous children described in THE LANCET of May 30th, 1903, p. 1551. The Waldschule is situated in a pine forest and comprises a variety of buildings. There are pavilions for the kitchen and other domestic purposes, a large hall where the children remain in bad weather, departments for bathing and gymnastics, a playground, and last, but not least, a school pavilion. The staff consists of a nurse who sees that the children have proper food and exercises supervision, a principal and four teachers, and a visiting medical man. Only two and a half hours are allowed for daily lessons apart from the instruction in natural science, gymnastics, and singing which is given in the open air. The rest of the day is spent by the children in the playground and in the forest under the care of the teachers. 120 feeble and anæmic, but not distinctly sick, children have been selected out of the Charlottenburg municipal schools for the Waldschule by the school medical officers. The teachers and the children arrive early in the morning, are supplied with food by the school, and return home in the evening. This innovation in the school system is certainly a good one and deserves to be imitated in other places on a larger scale.

The late Professor Weigert.

Professor Carl Weigert, chief of the pathological institution of the Senkenberg Academy at Frankfort, and one of the leading pathologists of Germany, died in that city on August 4th. His first work had reference to the staining of animal tissues by aniline colours—a method devised by him which has now become one of the most important processes in microscopical and bacteriological research. His researches on the neuroglia, on necrosis by coagulation, and on the proliferation of cells caused by external irritants are cardinal points in pathological anatomy. His investigations on the subject of tuberculosis, though carried on previously to Professor [illegible] means out of date. Professor [illegible] ünsterberg (Silesia) and studie [illegible] of Breslau, Berlin, and Vienna. On the completion of his medical curriculum he became an assistant to Professor Waldeyer at the Breslau Pathological Institution and at the Breslau Medical Clinic. When Professor Cohnheim, the celebrated pathologist and Professor Waldeyer's successor at Breslau, was called to Leipsic to become ordinary professor of pathology at that University, he only accepted this appointment on condition that Dr. Weigert should at the same time be appointed as his assistant. In 1879 Dr. Weigert was promoted to be extraordinary professor at Leipsic. In 1887 after the early death of Professor Cohnheim he was not appointed as his successor by the Saxon Government, although the Leipsic medical faculty was unanimously in his favour, and he therefore left Leipsic for Frankfort where he passed the remainder of his life as chief of the Senkenberg Pathological Institution.

William Wallace Wood, London Hospital; Edward Musgrave Woodman, St. Bartholomew's Hospital; and Harold Addison Woodruff, Birkbeck College.

At the intermediate examination in medicine for external students held in July the following candidates were successful:—

Laurence Ball, University of Birmingham;
University of Leeds; Ernest Frederick Fi
Sheffield; Robert Applegarth Hendry, U
James Ernest Middlemiss, University of Leeds; Edward Selby Phipson, University of Birmingham; Harry Richardson Rawlings, University of Leeds; Arthur Toulmin, Victoria University; Arthur Henry Turner, University of Leeds; and Joseph W. James Willcox, University College, Bristol.

Special Examination in Organic Chemistry only.—Kathleen Baylis, University College, Cardiff; Maud Bennett, London (Royal Free Hospital) School of Medicine for Women; Alfred Bernstein, Victoria University; Edward Wrigley Braithwaite, University of Leeds; John Webster Bride, Victoria University; Bertie Isaac Cohen, St. George's Hospital; Stanley William R. Colyer, Charing Cross Hospital; Charles Harley Crombie, private study; Elkin Percy Cumberbatch, University of Oxford; Arthur Davies, Westminster Hospital; Trevor Berwyn Davies, University College, Cardiff; Canut Deuntzer, Middlesex Hospital; Donald Frederick Dobson, University of Leeds; Josiah Rowland B. Dobson, University College, Cardiff; Maurice Rowland Dobson, University of Leeds; Evan Parry Evans, University College, Cardiff; Frederick Pearson Fisher, University of Birmingham; Arthur Fothergill, University of Leeds; George Blenkhorn Harland, Guy's Hospital and University of Durham; Clement H. Heppenstall, University of Leeds; Howell Tylford Howells, University College, Cardiff; Robert Henry Hatten Jolly, Charing Cross Hospital; Arthur Rocyn Jones and Evan J. Goronwy Jones, University College, Cardiff; Hugh Braund Kent, Northern and South-Western Polytechnics; John Lewis, University College, Cardiff; William Ernest Lord, University of Leeds; Theodore Henry Mason, St. Bartholomew's Hospital; Constance A. Mortlock-Brown, London (Royal Free Hospital) School of Medicine for Women; Vincent Moxey, King's College and University College, Bristol; Edward H. Allon Pask, University College, Sheffield; Alfred Alex. Webster Petrie, University of Edinburgh and Edinburgh Medical School; William Joseph Petty, Dan Arthur Powell, and Laura Gertrude Powell, University College, Cardiff; Percy John Probyn, Charing Cross Hospital; Albert Edward Quine, Victoria University; David Ranken, University of Durham; Alfred Richardson, University of Leeds; Arthur M. Marsh Roberts, University of Liverpool; Kenneth Robinson, Victoria University; Harry Dudley Rollinson, University of Birmingham; Arthur Denys Rope, Middlesex Hospital; Norman Guy H. Salmon, Charing Cross Hospital; Alice E. Sanderson, B.Sc., London (Royal Free Hospital) School of Medicine for Women; Frank Sholl Scott, and Latimer James Short, University College, Bristol; George F. Rawdon Smith, University of Liverpool; Horace Elliot Rose
Stephens, Victoria University; Gra
minster Hospital; John Thompson,
Tilly, Cuthbert
College Alwyn
Victori Arthu
Birmingham; and Henry Whitehead, Victoria University.

This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

SOCIETY OF APOTHECARIES OF LONDON.—At the examinations held in August the following candidates passed in the subjects indicated:—

Surgery.—R. H. Cooper (Section II.), Charing Cross Hospital; A. W. S. De Vine (Sections I. and II.), Birmingham; E. F. W. Hoare (Sections I. and II.), Liverpool; A. C. Story (Sections I. and II.), St. Mary's Hospital; and R. H. Terry (Section I.), Guy's Hospital.

Medicine.—G. B. Messenger (Section I.), Westminster Hospital; C. S. Scott (Section II.), St. Bartholomew's Hospital; I. C. Thorburn (Sections I. and II.), Liverpool; A. B. S. Todd (Section II.), Leeds; and S. H. R. Welch (Sections I. and II.), Charing Cross Hospital.

Forensic Medicine.—C. W. S. Boggs, Leeds; E. F. W. Hoare, Liverpool; J. E. Jones, Bristol; I. C. Thorburn, Liverpool; and H. M. Waller, St. Bartholomew's Hospital.

Midwifery.—W. G. H. Cable, London Hospital; and W. R. Elliott, Cambridge and St. Thomas's Hospital.

The diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: R. H. Cooper, A. C. Story, A. B. S. Todd, and S. H. R. Welch.

UNIVERSITY OF OXFORD.—The following degrees in medicine were conferred during the summer term:—

Doctors of hrist Church; Edgar W.
Willett, ers, Brasenose College;
Gustav J Arthur E. Boycott and
John D.
Bachelors Billinghurst, St. John's
College; A. F. Hertz, Magdalen
College; College; J. H. Thomas,
Trinity College; R. D. MacGregor, Exeter College; and P. A. Mansfield, Keble College.

Degree days are announced as follows for the coming term: Thursday, Oct. 20th; Thursday, Nov. 10th; and Saturday, Dec. 17th. Examinations for scholarships offered in natural science will be held on Dec. 6th at Balliol College, Christ Church, and Trinity College; on Dec. 13th at Lincoln and Magdalen Colleges; on Jan. 17th, 1905, at Jesus College; and on March 14th, 1905, at Keble College.

BIDEFORD DISPENSARY AND INFIRMARY.—The annual house-to-house collection of 1904 for the Bideford Dispensary has just been made, with the result that over £100 has been added to the funds of the institution.

ROENTGEN RAYS FOR MOSCOW.—The Moscow town council has ordered a Roentgen-ray cabinet at a cost of £150, inclusive of dynamo, for the use of the hospital sent by the town to the Far East. This apparatus will be under the control of the manager of the hospital, and if it proves to be satisfactory more will be ordered both for the hospitals in the town and the one in the Far East.

THE STILLBORN OF WARSAW.—In the suburbs of Warsaw, says the *Novoe Vremya*, the percentage to the births of stillborn children is 15. This excessive infant mortality is mostly due to the want of accoucheurs whose place has to be filled with self-styled nurses. In the suburb of Volya alone the number of stillborn children in ten years has been over 500.

THE LATE DR. JOHN SUTHERLAND.—Dr. John Sutherland of Netherfield, Nottingham, died on July 24th, in his forty-fifth year, after a very short illness. He was a native of Airth, a village in Stirlingshire, and his medical education was obtained at Edinburgh University where he graduated as M.B. in 1891. About 11 years ago he went to Netherfield, practised in partnership with Mr. J. T. Knight of Carlton-Gedling, and soon had many patients. Dr. Sutherland was a man of a good presence, rather over the average stature, and prepossessing in his manner; he was everywhere very popular and by his patients he was deservedly esteemed. The funeral, which took place at Carlton cemetery on July 26th, was very largely attended.

A HOSPITAL CURIOSITY.—On April 28th, 1903, a house-breaking firm made a unique discovery under the foundation stone of the old Royal Waterloo Hospital for Children, which they were razing to the ground. The foreman on removing a large piece of Portland stone, on which there was no inscription, discovered a glass tablet with the names of the founders, dates, and other details. There were also a small copper coin and a copy of the annual report of the hospital for the year 1822, contained in a bottle, and all in an excellent state of preservation. Among the patrons and vice-patrons were the following interesting names: The Duchesses of Kent, Northumberland, and Princess Augusta; the Dukes of York, Sussex, Grafton, Rutland, Beaufort, and others; Sir Robert Peel, Sir Humphry Davy, and other well-known people.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The following gentlemen have been elected as officers and members of council for 1904–05:—President: Mr. C. M. Tuke. Vice-Presidents: Mr. C. R. B. Keetley, Mr. W. P. Barrett, Dr. G. H. D. Robinson, Mr. J. R. Lunn, Dr. E. Furniss Potter, Mr. E. Bromet, Dr. G. P. Shuter, and Mr. H. Webb. Council: Mr. R. Pollock, Dr. A. M. Ross Sinclair, Mr. G. A. Garry Simpson, Mr. H. Percy Dunn, Mr. W. McAdam Eccles, Dr. E. P. Paton, Dr. E. A. Saunders, Dr. A. J. Rice Oxley, Dr. J. A. Mansell Moullin, Dr. A. Morison, Dr. A. E. Russell, and Dr. C. Buttar. Treasurer: Mr. T. Gunton Alderton. Secretaries: Dr. Andrew Elliot and Dr. W. H. Walter. Librarian: Mr. H. W. Chambers. Editor of Journal: Dr. Leonard C. T. Dobson. Editorial secretary: Mr. J. G. Pardoe.

ERRATUM.—In the list of the examination results of the University of Liverpool in THE LANCET of August 13th the name "D. T. Parry" given as having obtained the Diploma in Public Health should read *D. T. Barry*.

Notes, Short Comments, and Answers to Correspondents.

SLUM DWELLINGS AND SANITATION.

As a rule the slum-property owner who leaves his premises in an insanitary condition deserves no mercy, but we have always been willing to allow that in some instances his desire to do right is annulled by the conduct of his tenants. For instance, if water-closets are put in they are made filthy by the habits of the tenants. They are used as sinks and as receptacles for all sorts of waste and consequently get blocked. Dr. John Robertson, the medical officer of health of the city of Birmingham, in his report for the second quarter of the current year, has an interesting little note upon this question as it arises in Birmingham. The following are the arrangements that were made and we congratulate Dr. Robertson and his staff upon the work which they have done and the good results which they have obtained. The report says:—

> "One alteration made during the quarter consisted in detailing two of the court cleansers to go round and inspect the water-closets in the poorer districts with a view to getting the tenants to keep them clean, free from blockage, and with the doors locked. Distinctly good results have already been obtained from this frequent inspection, and it is hoped that in this way it will be possible to educate the lower classes to do their part in looking after the closets which have been provided for them at a considerable expense by the owners of the property.
>
> The following figures give some idea of the work done by these two men during the quarter.
>
> | | |
> |---|---|
> | Number of water-closets visited ... ... | 27,545 |
> | " found with doors unlocked ... ... | 13,890 |
> | " found with dirty floors ... ... | 1370 |
> | " found with dirty seats ... ... | 1129 |
> | " found with dirty basins ... ... | 5857 |
> | " found defective ... ... | 413 |
> | " found choked ... ... | 1082 |
>
> In each case where the closet was found to be dirty the persons using it were asked to put it in order, and in most cases this was sufficient. Where, however, the closets were frequently found in a filthy condition notices have been served, and legal proceedings will be taken if necessary."

CLOTHES AND PHYSICAL DEGENERATION.

A CORRESPONDENT signing himself "S. H. C." has written to the *Daily Chronicle* on August 17th concerning the above subject. He states that whilst the masculine physique is deteriorating the female figure is growing taller and better developed. In his opinion there is a certain well-defined reason for this difference which is receiving little if any attention. During the last 25 years he has observed some 7000 children in our elementary schools, and this observation has led him to the conviction that the matter of clothing needs special investigation. Girls, he says, are clothed in loose garments which are frequently washed. Boys, on the contrary, are dressed in tight-fitting cloth or serge garments, and these in most cases are never cleaned from the time when first made until the day when they literally drop off. He considers that if it were made compulsory that boys should be dressed in loose, clean clothes we should probably hear less about the degeneration of the race. We think that "S. H. C." has put forward a theory which is to some extent plausible. The accepted reason why the women of the last 20 years or so have grown taller than their mothers is that they lead different lives, but neither the fact nor its explanation is free from doubt. With regard, however, to the clothing of school-boys there can be no doubt that the school-boy of the lower and even of the lower middle classes wears clothes which certainly in many cases are anything but clean. Anyone who has had anything to do with boys' schools knows the peculiar smell of unwashed cloth clothes. It is probable, too, that in the case of the humbler classes of society the cloth of which their clothing is made is, to begin with, manufactured from shoddy, a material of which the components have seen their best days long before they start on their new career as cheap cloth. All this is true, and such clothing compares from a sanitary point of view badly with the often washed prints worn by girls; but we doubt if "S. H. C." has really furnished a cause of stunted growth.

ACCOMMODATION FOR RUSSIAN INSANE.

THE *Novoe Vremya* observes that the protection of the insane in St. Petersburg is of a deplorable character. All special asylums are full up, whilst it cannot be hoped that the request of the council to have district asylums built at Government expense will be settled soon, though application has been made in that sense. But the city infirmary committee have intrusted the chief medical men of the city infirmaries to work out the question of the improvement of the accommodation for the insane in the capital, as well as the installation of special infirmaries for dipsomaniacs. The urgency of this question is substantiated by an article that appeared in the *Novosti* some time ago headed "People in Chains," in which the writer stated, inter alia, that there were about 1500 insane in the Province of St. Petersburg and that for want of public arrangements for their care they are at the charges of their friends who care for them in numerous cases under most cruel conditions, some 400 being kept in chains by their relatives in huts, and some of them, the very violent, have to be caged off. He states that the chained condition of many has lasted from 10 to 15 years. Numbers have lost the power of speech and can simply howl and grind their teeth, while they lie on the ground like wild animals. The writer opens his article with the observation that "It is strange, but true, that in the large and wealthy government of St. Petersburg there is not even one infirmary for the diseased in mind."

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly recommend me a home or institution where a patient of mine (a boy, aged 14 years) can be placed? He is feeble-minded but can read and write and is capable of being trained; is obedient but requires discipline. Roman Catholic home, London or south coast, preferred. Terms must be moderate.

I am, Sirs, yours faithfully,
E. T. CROUCH, M.R.C.S. Eng., &c.

Stoke House, Gosport, Hants, August 21st, 1904.

THE APPEAL ON BEHALF OF MISS E. B. PELLATT, L.S.A.

THE treasurer, Surgeon-Colonel F. H. Welch, 8, Brandram-road, Lee, Blackheath, S.E., begs to acknowledge the receipt of the following sums, additional to those already reported:—

SCHOOLS FOR FEEBLE-MINDED CHILDREN.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if any of your readers will give me the address of a good school to which to send a feeble-minded girl, nine years of age. The parents are able to pay a fair fee—say up to £80 a year—and would prefer a school within easy reach from Llandudno.

I am, Sirs, yours faithfully,
EDWARD GOODDY.

Glenthorne, Trinity-square, Llandudno, August 19th, 1904.

MORE ALLEGED ABORTIONISTS.

AT Marylebone police-court on August 27th Sarah Elizabeth Allen, of Dornfeld-street, West Hampstead, was charged on remand with performing an illegal operation upon a young woman, and Ellen Stoneman, of Chesterton-road, North Kensington, was charged with aiding and abetting her in committing the offence. Mr. Plowden committed the prisoners for trial.

◆

In suspense.—No medical man is "obliged by law" to attend any case to which he may be summoned unless the patient is under his care in his capacity as medical officer to a hospital, workhouse infirmary, or other institution, or unless he be a naval or military medical officer on duty, or a police surgeon, or other paid medical officer. His obligation then arises out of his undertaking to perform the duties of a post which he has accepted and in which such duties are naturally involved. The obligation of a medical man in ordinary practice to attend his patients arises out of a contract to do so which may be express or implied and for the breach of which he is liable, as they are liable to pay him for his attendance. Whether his putting off his attendance to suit his convenience would be a breach of his duty must obviously depend upon circumstances. The General Medical Council may remove from the Register the name of a medical practitioner whom it may adjudge to have been guilty of infamous conduct in any professional respect. The question whether his conduct has been such is a matter of fact which the Council decides according to the evidence in the particular case before it.

H. A.—The answer to our correspondent's question depends entirely on the terms of the contract between the parties and his best course is to consult his legal advisers. As there are proceedings pending he could, if he has a right to them, probably take some steps in the existing action for the purpose of obtaining either delivery over of the books or their inspection.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* TO THE EDITORS and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private informa-
t addresses of
t
We

Local papers containing reports or news paragraphs should be marked and addressed To the Sub Editor

Letters relating to the publication sale and advertising departments of THE LANCET *should be addressed ' To the Manager*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index to Vol I of 1904 which was completed with the issue of June 25th and the Title page to the Volume, were given in THE LANCET of July 2nd

VOLUMES AND CASES

VOLUMES for the first half of the year 1904 are now ready Bound in cloth, gilt lettered, price 18s , carriage extra

Cl ears numbers are also ready
y post 2s 3d
to the Manager, accompanied by remittance

s
wh r
at their Offices 423 Strand W C are dealt with by them ? Subscriptions paid to London or to local news agents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers by sending their subscriptions direct to THE LANCET Offices will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions post free either from THE LANCET *Offices or from Agents* are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France - J. ASTIER, 31, Rue Bapts, Asnières, Paris.

An Address

UPON

THE SURGICAL TREATMENT OF ACUTE INTESTINAL OBSTRUCTION.

By ARTHUR E. BARKER, F.R.C.S. Eng.,
SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

IN considering this subject it will be well in the interests of brevity to define at once as comprehensively as possible the factors in obstruction which we have to treat surgically. These may be conveniently arranged under three heads. Some are purely (1) mechanical or anatomical factors; some are (2) physical factors; and some, again, are (3) vital factors. It would be impossible in the short time allotted to us to deal with all these in all their bearings and only the most important of each can be noticed.

1. *Under the head of "anatomical factors" will come the* consideration of the part of the intestinal tract which is the seat of the stoppage. This has an important bearing upon the treatment in so far as it claims the greatest promptitude of action and the most delicate handling of the parts involved. It is well known that the higher up the obstruction the earlier and the more acute, speaking generally, are the symptoms. On the other hand, the lower down the stoppage the greater the amount of retained matter and the more septic is it, while marked symptoms set in as a rule later. It is also almost certain that operations involving structures high up in the abdomen make a heavier demand upon the patient's powers than those done on parts low down. The character of the obstruction may best be placed perhaps under the heading "mechanical," whether it be a band, a volvulus or an intussusception, or an inclusion of bowel in one or other of the several pouches of the peritoneum. All these variations in the form of mechanical cause of obstruction have an important bearing on the treatment and must be constantly borne in mind, though we cannot dwell upon them here. It is enough to say that they are relatively the least important of all the factors. They have to be removed and this is a matter of mechanics and comparatively easy.

2. Of far more importance are the factors which may be grouped under the head of "physical changes" in the bowel. These include the anæmia at the point actually constringed, the venous engorgement of the parts distal to the constriction which is common, the consequent œdema, thrombosis, and frequently sphacelus or ulceration of that portion which are inevitable if there is delay in the treatment.

3. But under the heading "vital changes" come the most important factors of all in stoppage of the bowels. It may be a simple matter to find out and to divide a band, to untwist a volvulus, or to unravel an intussusception or other mechanical obstruction and thus to relieve the venous engorgement and its attendant physical evils. But in many, if not in most, of the cases of obstruction as they reach the surgeon the trouble does not end here. We have still to contend against both local and general "vital changes" in the body and these, I venture to think, are nowadays our greatest difficulty, since the dangers of mere opening the peritoneum have receded into the background. Above an obstruction, say low down, we have much retained fæces. In these we have swarms of bacteria existing under the most favourable conditions for multiplication. The retained matters are being constantly driven against the blocked spot by peristalsis and as a consequence the bowel becomes more and more congested and hypersecretion takes place. The micro-organisms fabricate in time large quantities of toxins for which there is no escape. Consequently, they are absorbed into the system by the usual channels, producing profound general depression of vitality with fever and often lung and kidney complications, and besides this soaking the congested bowel wall for a long stretch above the constriction, further devitalising it, causing paresis or paralysis of its muscular tissue, and preparing the way for that migration of bacteria through the bowel wall into the peritoneum which we now know takes place even without any breach of continuity if the vitality of the bowel has [illegible] As a consequence we have in [illegible] infection of the peritoneum even [illegible] Moreover, after an obstruction has been relieved such peritonitis may start from an unopened bowel soddened with toxins and loaded with putrid material which in its paralysed condition it is unable to get rid of by propulsion.

All these factors are met with in varying degrees in almost every case of intestinal obstruction with which surgeons come in contact from that caused by a band to that due to a volvulus. And if the surgeon is to treat the case rationally they must all be borne in mind and be met by special measures in each case. It will only be possible here to sketch in the merest outline the surgical methods to be employed in dealing with such conditions on the reasoning already given in brief.

Obviously in cases where an early diagnosis has been made and few or none of the *physical* or *vital* changes alluded to are present our only care is to restore as soon as possible the anatomical integrity of the intestinal tube. We have nothing to fear from the physical or vital changes in the gut, peritoneum, or system generally. This is quite clear from our experiences with recently strangulated herniæ. We divide the constriction, replace the bowel, and expect and obtain, as a rule, rapid recovery. The same is the case where a band is divided *early* in a case of *internal* strangulation or where an intussusception is unravelled or a volvulus untwisted. It is purely and only a question of mechanical relief. Clearly, then, it is unnecessary to labour the claim for an early diagnosis and prompt surgical action. More depends upon these than upon any particular method or details, how[illegible] delay both in diagnosis and [illegible] too frequently takes place in cases of intestinal obstruction and when at last an operation is undertaken we are face to face with physical and vital conditions, local and general, which continue to be dangerous or even disastrous after the mechanical obstruction has been relieved. What can be expected of surgical interference where a bowel for a long distance above the obstructed point is in a state of paresis or complete paralysis and is loaded with pints of putrid, fermenting fluid and the walls of which *have almost or entirely lost their vitality? Such a bowel after* release of the obstruction may subsequently necrose and perforate, or, even without any breach of continuity, its loss of vitality may permit the passage through it of virulent organisms present in millions which do not pass through healthy walls. How little can surgery do when as a consequence of these changes the system is saturated with toxins depressing the functions of every organ and tissue in the body and probably already initiating well-known pulmonary and renal diseases. Surgical interference involving a long operation undertaken under these conditions is *necessarily* and *inevitably* imperfect in the highest degree and, as we know, is often futile. As if to emphasise this point, while writing the foregoing sentence a few evenings ago I was telephoned for to see a case of intestinal obstruction at hospital which had just arrived. I put down my pen and went at once, but only to see the patient expire just as I reached the bedside after getting rid of a large quantity of stercoraceous vomit. I have since heard that the post-mortem examination showed a band obstructing the ileum low down and that the latter for a long distance above was in a most unsound condition and could not have been left in the abdomen with any prospect of recovery.

But in turning now to the details of the operative treatment, let us suppose that a case though bad has not yet reached quite such a hopeless stage as that just mentioned and let us try to formulate rules of procedure. This can be modified according to the stage of obstruction at which the patient has arrived.

The first thing is to ascertain whether the stomach has been emptied. It may be stated by the friends that vomiting has just taken place, but this should not deter us from using the stomach-tube and we shall be surprised in many cases by the quantity of foul matter which can be removed even where vomiting has been free just before. To leave this [illegible] intestine itself, which, already paralysed, is after operation in the worst possible condition for propelling its contents downward. This washing out should be repeated over and over again before the patient is anæsthetised.

The mouth and throat should then be washed out with some antiseptic fluid, such as chlorate of potash or sanitas, and a warm drink of brandy-and-water should be given if the stomach is empty. If the patient is very feeble it is also sometimes of the greatest use to instil subcutaneously half a litre of a 5 per cent. solution of glucose or of normal saline. This has not only the effect of supplying the tissues with the water which has been lost by vomiting, and by the lungs, skin, and kidneys, but also gives the latter organs a better chance of eliminating toxins in diluted form and consequently with less damage to themselves. The glucose, too, is a food and in 5 per cent. solution is isotonic with the blood and easily borne by the tissues into which it is injected. If glucose and normal saline are used together the first should be 2½ per cent. and the salt 0·45 per cent., which I have found to be isotonic. Alone they are respectively 5 per cent. and 0·9 per cent. A rectal injection of warm normal saline solution and half an ounce of brandy is also desirable.

The further preparation for operation includes all the precautions of asepsis. The society has so recently had the advantage of hearing Mr. C. B. Lockwood upon this subject that nothing further need be said upon it now except that I should like to express the conviction, based upon an experience of asepsis pure and simple for many years, that the less *chemical germicides* are used once the skin has been cleansed the better for the result of the operation. They should never be used within the abdomen.

The patient should, of course, be kept as warm as possible by being wrapped in wool and surrounded with hot bottles, the room being heated to at least 70° F.

The choice of an anæsthetic is a matter for each surgeon to decide for himself. But for my own part I feel more and more every day that these operations should be done under local analgesia, wholly or in part. This feeling is not due to any special fear of ether or chloroform in ordinary cases. But in those under discussion, where the respiration is often embarrassed by a distended abdomen and where the vital powers are lowered by want of food, vomiting, and in many instances by advanced toxæmia, I have a very strong conviction that the chances of recovery are very much diminished by general anæsthesia. It is an easy thing now to render the skin, muscles, and neighbouring peritoneum absolutely insensitive to pain, and as the intestines themselves are insensitive they can be cut, stitched, and handled without any suffering. The root of the mesentery and its lateral reflection are the crux and if it is necessary a little chloroform can be given for the necessary intra-abdominal manipulation which may only last a few minutes. But it is a very different thing to give a general anæsthetic for, say, five minutes and to keep a patient even lightly under for from 50 to 100 minutes. In one case there are usually no depression and no after-sickness: in the other there are usually both. For children and for certain nervous young people local analgesia is unsuitable, but this class of patients, as a rule, bear chloroform well. It is for the mature, and particularly the aged, that I would plead for a more extended use of local analgesia. In its most recent development it is an enormous improvement on the form it took up to a year ago. But the details must be mastered by much practice in a variety of cases before it can be employed with confidence.

When the abdomen is opened it is a most valuable rule to search first of all for a loop of *empty* bowel in the right iliac fossa as a guide to the obstruction which in the majority of cases is low down. This is a far easier method of finding the point of stoppage than to search along the distended gut which is proverbially difficult to manipulate and to control.

The actual release of the obstructed bowel is a purely mechanical matter and will be carried out by different surgeons in various ways but it is certainly easier to work from the empty bowel towards the distended portion than *vice versâ*. If a band is found it is a simple thing to divide it. If an intussusception is present we only follow the path of wisdom if we adopt Mr. Jonathan Hutchinson's advice of long ago and always attack it from the distal end and avoid all pulling from the proximal. Only one other point I would venture to plead for in this connexion—namely, that all this should be done as far as possible within the abdomen. I am no friend of eventration and believe it to be in most cases not only hurtful but unnecessary. One is tempted, of course, to do it in cases of great distension. But even here it is better to draw forward a small portion of the most distended gut and to slit it open over a basin and to empty it than to expose large tracts externally. It must not be forgotten that the mere evacuation of gas and liquid fæces revives the patient and where great asthenia is present, of course, in some cases the operation should go no further until the abdomen is emptied, but such cases are in my experience few nowadays.

But short of these almost hopeless cases others give us *nearly* as much anxiety where several feet of bowel above the obstruction are distended, paralysed, sodden, and discoloured. From experience we know that this bowel is most probably ulcerated internally not only at and just above the constriction but often for a foot or two upwards. What are we to do in such a case? To return the bowel after simply relieving the obstruction is to allow pints of fermenting fæces either to remain stagnant or to escape into the empty, and as it were hungry, bowel below with all the risks of more abundant absorption of the poison than before. If this is not done one of two alternatives remains. Either we must temporarily drain the distended gut or boldly resect several feet of it with their contents and unite the upper and lower portions. Of the two I prefer the latter course. By this means we remove at one sweep all the septic bowel and its contents and with these the greatest dangers to the patient. These are the dangers of peritoneal infection with or without sloughing or perforation of the bowel and of toxæmia from absorption of its liberated contents as they pass into the intestine below. For the last five years I have generally acted on this principle with results far superior to any I was able to obtain previously. But I have so recently written upon this subject in detail with an analysis of all the cases which led to this rather bold conclusion that it is natural to hesitate to take up your time by going over the ground again.[1]

One point is perfectly clear from the experience of these recent cases—namely, that there is no more *shock* from removing several feet of bowel than there is from taking away a few inches. Again, we need to be reminded that the anastomosis of the remaining parts is equally easy or difficult independently of the length of the part resected.

Permit me to allude to two cases of acute intestinal obstruction in which this course was adopted with perfect success. The gut removed in each case is on the table. The first was that of a feeble old woman, aged 78 years, with an intermitting pulse when admitted. The cause of the obstruction was a band and the gut for quite two feet was black and almost gangrenous and was surrounded by more than a pint of dirty stinking fluid which gushed out when the abdomen was opened. Here I excised five and a half feet and joined end to end. There was *no* shock and recovery was perfect under one dressing. The patient returned to show herself quite well a year later and is, I believe, still well four years after operation. (N.B.—The bowel was extensively ulcerated above the obstruction.) The next case was that of a woman, aged 52 years, with a gangrenous femoral hernia. I had to go more than six feet above the obstruction to find fairly healthy bowel. Lateral anastomosis was done and six and a half feet of ileum were cut away between the point of junction and the obstruction. Here, too, there was no shock and the recovery was complete. But it is interesting to note that there was much very foul diarrhœa for some days. On the third day after operation the patient had three copious putrid stools, on the fourth day she had five, and on the fifth day six, and then there was no action of the bowels until the ninth day, but still a loose motion, though not so foul. Here the evacuations must have come from above the point of junction, for the bowels were well opened on the fourth day of strangulation after stercoraceous vomiting had set in. Neither of these cases could have recovered if it had been possible to replace the bowel loaded with putrid fæces. They would have died either from perforation or toxæmia, or from the exhaustion of diarrhœa in getting rid of the festering material stored up above. Let it be remembered that if the bowel be distended to only two inches in diameter every foot of it will contain more than one pint of putrid material.

On the question of shock from these operations I should like to be permitted to mention briefly one other case of recent occurrence. This was the case of a patient under the care of Dr. F. Roberts and was one of the worst cases of typhoid fever he or my other colleagues had ever seen The woman who was 33 years of age, was in the third week of the disease She had suffered from severe hæmorrhages, had had severe bronchitis and on the day of operation had a temperature of 105 6° F with rigors Symptoms of perforation having come on I was asked to operate Dr F J Poynton, who was kind enough to see the patient with me in the unavoidable absence of Dr Roberts, gave it as his opinion that she would die if a general anæsthetic was employed but that if an operation could be done under local anæsthesia without shock it ought to be done at once I opened the abdomen under β eucaine analgesia and found extensive gangrenous patches over a length of intestine and peritoneal effusion As all were covered with lymph and threatening to give way I resected the whole loop including 27 inches and joined end to end (specimen shown) Again according to the physicians in charge there was no shock and the next day the patient was decidedly better with improvement of pulse and temperature Fresh hæmorrhage set in later and she died as the result There was ulceration in the remaining gut and throughout the whole colon down to the rectum, and apparently several of these ulcers had furnished the fatal hæmorrhage The line of suture was perfect in every respect The pulse had improved until the bleeding set in I only mention these cases from among a number to illustrate the fact that there is not necessarily any shock from enterectomy

The conclusions I should venture to draw from the foregoing reasoning are these 1 That too much stress has been hitherto laid upon the mere removal of the mechanical
ition of the putrid
is is only to repeat
, Mr Greig Smith
2 That the older method of emptying the bowel by establishing an artificial anus is unsatisfactory as the bowel is in a state of paresis or complete paralysis and only expels its contents very slowly and until it is cleaned out the cause of
the
Mr
the
• us this, and that this method of treatment is unsatisfactory any careful analysis of a long series of cases reveals as I have endeavoured to show in the paper just referred to 3 That the best course in many of these cases probably in all that are still within the reach of any operative procedure is to resect the tract of paralysed and distended bowel at once This would not of course apply to recent cases where the bowel is not seriously damaged by the retained fæces and is manifestly sound at and above the seat of obstruction But excluding these there remains unfortunately a large group of cases where we are face to face with a disastrous state of things which requires very bold action on our part

On the question of drainage of the abdomen or not in these cases each surgeon will act upon his own judgment in particular cases For my own part I am in most cases in favour of closing the abdomen at once unless there be general peritonitis having a great belief in the power of the peritoneum to take care of itself The reasons for this would lead us too far But I must admit that I have lost a case almost certainly from closing without drainage after resection of the diseased part

The after treatment of these cases is of extreme importance They should in all instances sit up in bed from the first as much as possible and only lie down, preferably on one side or the other for sleep so as to overcome the tendency to hypostatic pneumonia [3] They should begin at once to take a mixture of ten grains of carbonate of bismuth three times daily which with Kocher I believe to be the best intestinal antiseptic Albumin water with one drachm of brandy, should be given from the first by the mouth in small quantities and nutrient enemata and instillation under the skin of normal saline solution or 5 per cent solution of glucose is recommended as a routine Half a litre morning and evening may be given if necessary Hitherto perhaps we have been too sparing of food by the mouth In small quantities and light it may be given early at all events in cases where the diseased bowel has been resected

In many cases diarrhœa is a very troublesome complication It is the natural effort to discharge a quantity of putrid retained fæces and is often mixed with blood and mucus *It is not well to check it too much as this material* must be evacuated before the patient is safe Here the bismuth plays a useful part in cleansing the gut, and so arresting the diarrhœa

In some cases, especially intussusceptions the temperature rises to a high degree after liberation of the gut The explanation usually given of this is the passage into the circulation of blood which has been stagnant in the included bowel long enough to be saturated with toxins This is probably correct Cold sponging and warm drinks have proved the best treatment for this condition so far as I have seen in many cases If the fever is due to pulmonary emboli or pylephlebitis we can only sustain the general *strength by the use of the usual stimulants*

It must be obvious that in a subject such as this many other points might be discussed but time fails and only an outline can be given as a basis for debate

[3] The cases from which I excised 5½ feet and 6½ feet sat up at once and the old woman, 78 years of age was in an armchair by the fifth or on the sixth day

SOME REMARKS ON PYOSALPINX BASED UPON NOTES OF 23 CASES

By E STANMORE BISHOP, F R C S Eng ,
HONORARY SURGEON TO THE ANCOATS HOSPITAL MANCHESTER

A collection of cases of one kind is always interesting to those engaged in similar work, and still more so if it covers a number of years and so reflects to some extent the evolution of the operator s views and of the measures employed Although the number of cases is not large, inasmuch as cases occurring in connexion with fibroid tumours and some other complications are not included, it will be seen that the list extends in date from 1894 to 1903 a period of ten years During the last decade a great amount of activity has been devoted to pelvic surgery and the changes have been many and radical Thus in 1894 abdominal drainage by Keith s glass tubes was the rule after any operation upon structures in the pelvis, especially if any formation of pus was present The powers of the peritoneum with regard to the disposal of effete material were but imperfectly known and still less trusted and the differing virulence of pus was not so clearly appreciated as it is now Since these two facts have received the due recognition of their force the old idea that drainage was in all cases imperatively necessary has ceased to be dominant and the dangers of the employment of drainage tubes themselves have been more clearly recognised In Case 8 there can be but little doubt that the tube contributed to the production of a fæcal fistula by its pressure upon the bowel The same thing was threatened in Case 5 Glass tubes required frequent movement or they became impacted by the entrance of omentum or other structures into their openings below the surface They were rotated and slightly lifted from time to time During such movements it was very easy for a small knuckle of intestine to slip beneath their lower extremity and to become nipped between this and the concavity of the sacrum behind Moreover, the opening into the peritoneal cavity intended as a means of exit for matters within was of necessity also a means of entrance for bacteria from without and pus which had become sterile might easily become a nidus for the development of new and virulent organisms which thus were freshly implanted The fact that the long retention of pus in a closed cavity, such as the Fallopian tube became resulted in the death of the germs which had originally produced it, and that what was left was nothing more than a collection of fattily degenerated cells was for a long time but imperfectly understood and appreciated When it was understood the apparent necessity for drainage of any undetected and unremoved particles of such a fluid disappeared Then Clark, Muscatello and others demonstrated the wonderful powers of absorption of the peritoneum which when unhampered by the presence of drainage tubes, quickly cleared away all dangerous material from its interior, and the necessity, if this were to be complete, of the re formation of a perfectly closed cavity, in order that the necessary intra peritoneal currents might once more come into play

The presence of this glass tube was harmful in two other ways The more important was the fact that a weak point was thereby produced in the abdominal wall, from which a post-operative ventral hernia was almost surely developed. The presence of a glass tube projecting from the abdominal wall also necessitated the maintenance of the patient in a definite position. Material which had to be removed was supposed to drain towards the lowest point, the bottom of Douglas's pouch, from whence it was drawn up by an exhausting syringe, and in order that this might be the case it was necessary to keep the patient in such a position that the bottom of Douglas's pouch should always be the lowest point. All abdominal surgeons know what a difficulty there is in restraining the restless tendencies of a patient during the first few days after an abdominal section. The necessity for perfect stillness in one position amounts in some patients to positive torture, to say nothing of the probability of the formation of bed-sores over the bony points thus subjected to prolonged pressure. If for this alone the abandonment of the glass tube was a great relief to both surgeon and patient. And when Clark proved that in many cases the post-mortem examination showed that the tube itself had rapidly become inclosed in a surrounding sheath of lymph shutting off all the rest of the peritoneal cavity, whilst collections of pus existed around it, within a few centimetres of its circumference, thus demonstrating its inutility for the very purpose for which it was used, its retention at once became impossible. Muscatello demonstrated that foreign material was removed from the peritoneal cavity, when that was intact, by peritoneal currents which carried it towards the lymphatics of the diaphragm; that particles of carmine, for instance, injected into this cavity could first be recognised in these lymphatics and next in the mediastinal glands. Case 16 would appear to support the truth of these observations. Some infective material evidently found its way into the abdominal cavity in this case. The general cavity escaped in consequence of the measures adopted—accurate closure, followed by free purgation—and general peritonitis was averted, but a subphrenic abscess formed which required evacuation.

The difference in the intensity and duration of symptoms in various cases is noteworthy. Although in the majority some direct connexion between traumatism during labour or the poison of gonorrhœa could be detected, and a long period of invalidism traced between the date of infection and that of operation, during which symptoms were constantly more or less present, this was not the fact in all. In Case 16, already referred to, although two large pus sacs were found, no symptoms at all had been noticed and the patient declared herself to have been in perfect health until 14 days before admission to the hospital. (See also Case 23.)

One point in diagnosis is worth reference. Some years ago Cleghorn of New Zealand drew attention to the presence of a pulsating vessel in the fornix on the same side as an ectopic pregnancy and suggested that this would be found to be a differentiating symptom, marking such cases off from others in which a similar pelvic mass could be detected. But Case 5 would appear to show that any mass which from its position, or in consequence of superior adhesions limiting its upward development, is forced to press outwards and downwards, so as to displace the uterine artery in the same direction before it, will produce this vaginal pulsation; so that the value of this symptom as indicating the presence of ectopic pregnancy is greatly discounted.

The question of how best to attack these collections of pus, especially in acute cases, is a difficult one, and one in which the dispute between what may be called abdominal and vaginal operations reached its highest point. There seems to be little doubt that in an acute case when the virulence of the contained bacteria is still great, the removal of these sacs through the abdominal wall is extremely risky. Adhesions are plentiful and firm and the omentum has often been utilised to close some point of leakage such as the abdominal end of the Fallopian tube. Should the adhesions be sufficiently light to justify an attempt at peeling them off it is quite possible that a sudden gush of pus may signalise the removal of this safeguard, and this pus may reach healthy peritoneum and light up general peritonitis; such an escape of pus occurred in Case 15. Even if this does not happen the walls of the containing tube are greatly thinned by their distension and may give way at any stage during their enucleation. This occurred in Cases 7, 11, 12, and 16. Of course, the Trendelenburg position, by enabling the surgeon previously to pack in sponges which will absorb these fluids at once, has greatly minimised this danger, but it cannot be said to have removed it entirely. It is obvious that separation has to be done in advance of the sponges. If they could in all cases be previously packed below there would be no posterior separation to be done; and not only is this so, but occasionally the amount of fluid which suddenly escapes is so great as immediately to soak through the comparatively thin sponge, which alone can find space in which to lie, and so comes into contact with the raw surfaces produced and even with the unaltered peritoneal surfaces above. This risk is, of course, practically unimportant should the case be chronic, the bacteria dead, and the escaping liquid merely fattily degenerated débris floating in a sero-purulent fluid; but who can determine this beforehand? And if the bacteria are not dead, if the escaping fluid is still infective, possibly virulent, the risk is very great.

It would appear to be far safer to open these acute abscess cavities from below through the vagina. Case 11 was such a case as that referred to in the last paragraph. In Cases 17 and 21 the time which had elapsed since the date of infection was so recent and the patients themselves were so acutely ill that there could be little hesitation as to the route to follow. The pus was evacuated through the vagina and recovery was prompt and rapid, whilst the other patient (Case 11), whose pus sacs were enucleated through an abdominal opening, died. Some of these collections can be felt from the vagina and then, too, there is but little hesitation in coming to a conclusion; the real difficulty arises when they cannot be felt from this canal, when adhesions above prevent their descent into Douglas's pouch, and their removal in this direction necessitates the contemporaneous removal of the uterus also before they can be reached. Should there be any hesitation in doing this? Usually the inflammation which has produced the tubal or ovarian abscess has also so disorganised the uterus that its preservation simply means retention of a perpetual menace to the sufferer's health; if both tubes are mere pus sacs the uterus can never again, one would imagine, be of any service and may be sacrificed without any real loss. Even if this be admitted the difficulty in some cases may not be wholly removed. In one case, not in the present series, after removal of a fibroid uterus with two pus tubes the right ovary was found separated from the rest and adherent to the fascia over the psoas muscle in such a position that it could not have been reached and it is doubtful if it could even have been detected through the vagina even after the clearing away of the uterus; and another difficulty arises when the operation has to be undertaken, as it occasionally has, in women who have never borne children, whose vagina is therefore undilated, and in whom the hymen itself may be present. It is difficult to understand how the condition arises in such cases. One of the usual causes, septic infection after a labour or miscarriage, is obviously excluded in consequence of the anatomical conditions present. In many the suspicion of gonorrhœa seems to be equally impossible. Is it possible that masturbation in women may produce tubal inflammation? I am not aware of any cases which definitely prove this point; and, indeed, evidence which might settle the question would be extremely hard to elicit.

The duration of the operation in some of these cases is considerable. Although the time expended may be due to some extent to the personality of the operator it is not entirely so. Separations of adherent viscera, when these viscera contain septic material, as the intestines do, must be done cautiously and patiently. Undue hurry may easily lead to tearing of their walls and thereby the production of greatly increased and needless risk, whilst the duration of the work is also lengthened. In such cases the resultant shock is certain to be great. I have been much impressed by the notable effects produced by transfusion of normal saline solution in these cases. Case 22 undoubtedly owed its success to this measure; and I am inclined to look upon it, not only as filling the blood-vessels, which is its primary object, but as assisting markedly in the removal of any toxins rapidly from the system. But that it should be introduced into the veins of the patient is open to question. When necessity for it arises it requires to be done at once. By the very circumstances of the case the veins are empty, collapsed, difficult to find, and still more difficult to enter. Valuable time is lost in searching for, and then in introducing, the cannula *secundum artem*. It is far more easy, and therefore far more quickly effectual, to pass the hollow needle into loose connective tissue such as is found in abundance

beneath the breast or in the axilla; and, so far as I have
quickly utilised as it would be
vein. Moreover, if it is done
heat of the injection itself must

obtained;
may not carry into the system certain toxins from so septic a canal as the intestine which would be much better left outside. Such a possibility could not occur were the fluid merely absorbed from clean connective tissue.

Shock is, indeed, one of the greatest dangers immediately to be feared, and anything which lowers the vitality of the patient should be avoided if possible. Loss of bodily heat is one very potent factor in this direction. Most of our operations at the present date are carried out on metal tables. If these tables are heated sufficiently to remain warm during a long operation they must at first be uncomfortably hot. If they do not remain warm they will abstract heat from the patient lying upon them and so decrease his vital resistance. Many plans have been adopted to avoid this, but, so far as I have seen, without great success. If metal cases containing hot water are used they render that portion of the table which has to be raised in order to obtain
Trendelenburg position far too heavy. In this position a
the hottest point will be that towards which the wa
gravitates—that is, the shoulders, where it is not want
By dividing the metal case into several compartments t
may be avoided, but the whole thing is very cumbrous a
interferes with the sometimes rapid change of position required. Lately I have had a rubber bed constructed which is made up of a succession of transverse rubber cylinders containing hot water which has proved to be at once light, easily managed, and very effective. I feel certain that in numerous instances its use has made all the difference by preventing loss of bodily heat. In a case not many weeks since, in which the abdominal cavity was open for over two hours, the subsequent shock was extremely slight and recovery was correspondingly rapid.

tion was done and she was discharged
weeks later.

CASE 7.—Y, 80. Mrs. ——, aged 36 years, was admitted on August 28th, 1896. She had had three children and one miscarriage. When 16 years old she lost blood continuously for six months. She married when 18 years old and was first pregnant six and a half years after marriage. Her first child was born 12½ years previously, the labour being normal, with a good convalescence. A miscarriage occurred at five weeks 11½ years previously. The patient had "*inflammation*" for 13 weeks *following*; she got up for two days and had to go to bed again for 16 weeks. Her second child was born ten years ago, premature, at eight months. When six months pregnant she flooded and the vagina was tamponed. She nearly bled to death at the confinement. The child was born at 6 A.M. and the placenta came away itself at 9 P.M. Her third child was born *eight years ago at full time. For the first three months of pregnancy the menses appeared regularly. The membranes ruptured three days* before the birth of the child. She was in bed for a month afterwards with "windy spasms." Since this confinement there had been occasional dribbling of blood for five or six weeks at a time; this had been most marked during the last 12 months. The patient complained greatly of flatulence. There was no frequency of micturition. 14 days before admission she had a rigor; this had recurred several times since. Bimanual examination showed an apparently normal uterus, with a firm elastic mass on the left side, springing from the uterine fundus. On Oct. 2nd a median incision was made below the umbilicus, the patient being in the Trendelenburg position. On the left side of the uterus a very tense, adherent tumour of the size of a small orange was found. This was formed by the ovary which was converted into a pus sac, with very thin walls, which ruptured during separation. The pus was caught by sponges which had been packed in below. The left tube was closed at both ends and was distended by clear amber-coloured fluid. Both were removed and the abdomen was closed without drainage. Convalescence was delayed by uterine hæmorrhage which set in on the fifth day and lasted for six days, *when the uterus was dilated and curetted, some soft placenta-like* membrane being brought away. From this time improvement was rapid and continuous.

CASE 8.—L, 48. Mrs. ——, aged 33 years, was admitted on Nov. 14th, 1896. There had been one confinement seven weeks previously to admission. Rigors supervened on the *third day. Pain then was* felt in the right inguinal region. On admission bronchitic râles were heard all over the chest. Bimanually the uterus was found *to be fixed, with* two large, rounded, elastic, fixed masses, one on either side. Operation was postponed in order, if possible, to eliminate the bronchitis before this was done, but as the temperature rose steadily from 100° F. on admission to 103° with morning remission it was thought best not to *delay further. Operation was performed on Nov. 24th*, the patient being in the Trendelenburg position. A median abdominal section was made. The omentum was thickened and widely adherent. The appendix was adherent to the left ovary which was deeply embedded in firm adhesions. About an inch of small intestine was also *adherent and was separated with some little difficulty. After loosening* all these the left ovary was found to contain two abscess cavities, one in the centre and one near the surface. This was *removed with* the left tube which seemed merely inflamed and was not much changed. The appendical mesentery was matted up in such a way that two tubes appeared to spring from the cæcum. The appendix was removed and the stump was covered by peritoneum. The right tube *was very adherent, buried in adhesions, and greatly swollen.* After it was sufficiently loosened so that it could be brought up towards the surface sponges were packed around it and it was opened. About an ounce of pus was evacuated and then the empty tube could be further loosened, tied, and removed. There was free bleeding from the separated adhesions for a time but this soon ceased. A glass Keith's tube was placed in Douglas's pouch and the abdominal wall was closed around it. The temperature sank to normal during the night and remained so until the morning of the 26th, when it rose again to 101°, reaching 103·6° at 10 P.M. On the 27th it sank to 100° and continued below this until just before death, when after sinking to 97·4° it rose again to 102° on Dec. 5th, when death ensued. The pulse gradually and steadily *increased in rapidity from* 128 after the *operation* to 170 before death. The respirations ranged from 24 to 60. There was persistent and very distressing coughing from the time of the operation. Pus was found in the fluid withdrawn from the tube on the 26th and fæcal matter the same night. This became more and more in quantity up to the time of death. The bowels, however, *moved freely from Nov. 26th*, flatus having passed first on the 25th. Urination was free but pus was seen in the urine on the 26th.

CASE 9.—W. 104. Mrs. ——, aged 38 years, was admitted on Oct. 21st, 1897. See had had three children but no miscarriages. The eldest child was aged 15 years. *The perineum was torn.* The youngest child was aged 10 years. The last confinement was very painful. Every pregnancy had been associated with severe vomiting, sometimes of blood. The last child was suckled for 15 months. For six months the patient suffered from great pain in the hypogastrium and on the left side, especially on exertion. Since that time the pain had been less, though always present to some extent until five months before, when it again became more intense. She had never been wholly free from pain except at night, when she slept from 10 P.M. to 3 A.M., after which the pain prevented further sleep. In 1893 she consulted a surgeon who found retroversion and prolapse. The version could not be remedied even with a sound under chloroform. Pessaries and tampons were used. Relief was obtained by Thomas's glycerine pessary, which prevented the otherwise constant bearing-down, but produced frequent desire to urinate. Urination was painful on commencement; it would stop suddenly and then go on again. After urination there was pain for about an hour. Menstruation was regular, but the pain was always *worse at the period*, and this accentuation had been more marked since the pessary had been worn. She suffered also from piles, which bled a good deal.

CASE 10.—N. 103. Miss ——, aged 47 years, was admitted on Nov. 25th, 1897. She had always been regular, with some premenstrual pain. *She had complained for some months of pain in the* hypogastrium; this was dull and continuous, and from time to time there was acute pain on the left side, which passed down the thigh, mainly in front, along the course of the inner and middle cutaneous nerves. There was undue frequency in micturition and the pain was sometimes relieved and sometimes *increased by the act.* It was difficult to get any clear account of her symptoms but the acute pain was associated with vomiting. There had been habitual constipation. Recto-bimanual examination showed a virgin uterus, with an elongated elastic mass by the side in the position of the left Fallopian tube. This was extremely tender. The hymen was intact and the vagina was narrow. On Dec. 2nd operation was performed and commenced from the vagina. The bladder was separated and the uterine arteries were tied. The patient being turned into the Trendelenburg position a median incision was made. The small intestine was adherent to the anterior peritoneal wall. The tubes and ovaries were matted together and covered by adherent omentum. As it was evidently futile to attempt separation by this route and there existed a large *collection of* fluid in the left tube the patient was replaced in the lithotomy position and with great difficulty, owing to the narrowness of the vaginal canal, the uterus was removed. When the peritoneum was *opened about a pint of viscid orange-yellow fluid escaped from a cavity with smooth walls on the left side. This cavity and the vagina were* filled with iodoform gauze. Recovery ensued and the patient was in good health in April, 1904.

CASE 11.—Book 1, 83. Mrs. ——, aged 2
Jan. 17th, 1898. She had had no children
had never enjoyed good health and had ha
of age which left her ailing until 20 years ol
from anæmia. Later she had fair health until six months after her marriage, three years before; then she had "swelling of the ovary." In October, 1895, she contracted scarlet fever and was in a sanatorium for seven weeks. In September, 1896, she was chilled whilst at the seaside; a menstrual period occurred soon after and the flow was scanty and clotted; there was not much pain at that time but being constipated she took some senna which produced diarrhœa a
pain. This pain was most intense during the
wards; it was now not so continuous but when
as severe as at first. About a month after the pain began she commenced to lose weight; this improved a little on going to the seaside again in February, 1897, but fell off again. She had been confined to bed for the *last ten months and for nine months had had night* sweats. The left leg had been swollen, with some difficulty in full extension. The right was normal in size and movement. At the time of examination the patient was much emaciated with a hectic colour on the cheeks. The edge of the liver projected one and a half inches below the costal margin, was smooth, and without bosses. The spleen was not enlarged. Bimanually the uterus was found to be fixed with a firm, rounded, elastic mass on either side of it. Operation was performed on Jan. 20th, 1898, the patient being in the lith
narrow. The bladder was sepa
fornix was opened. This latter i
up a cavity containing about two
out. *The uterus* was *split compl*
either side down. The vagina was plugged with gauze. On opening the abdomen, after the patient had been placed in the Trendelenburg position, a few clots were found over the line of division in the vesico-uterine fossa. A loop of small intestine was found adherent to the *bladder and to the left iliac fossa and the adhesions, which completely* shut in the uterus and tubes, were so firm as to require division by the scissors, leaving a longitudinal raw surface on the bowel. An attempt was then made to draw upwards the uncovered uterus, but neither half would move. A large pus sac was seen on the left side. This was enucleated but was torn slightly in the process, fluid escaping on to a flat sponge placed behind. When this was done the corresponding *left half of the uterus could be brought up* and removed. The right uterine segment also became moveable and was taken away with fair ease. The right ovary was then shelled out of the bed of adhesions in which it lay and was found to be caseous. The whole pelvic cavity was then dried out and a large gauze drain was drawn through into the vagina, *its upper part being packed* into the pelvis in order to cover the raw surfaces which were unavoidably left. All vessels as divided were tied with fine silk and cut short. The pelvic peritoneum was left open, the gauze projecting through it; the abdominal wall was closed. There was very great shock. Transfusion and hypodermic injection of suprarenalin were given during the *operation*, and the latter steps of the operation were greatly hurried. There was no radial pulse on completion, and transfusion was again carried out on her return to bed, whi again given hypodermically. She recover e of events seemed favourable, but 24 hours again and *in spite* of fresh transfusion she died.

CASE 12.—Book 1, 73. Mrs. ——, aged 31 years, was admitted on May 5th, 1898. She had had no children or miscarriages. Menstruation had commenced at 14 years of age. She was suffering from typhoid fever at the time. She had never been irregular. The period occurred every three to four weeks and was always painful, but latterly *this pain had become more frequent and more intense.* The pain was felt in the hypogastrium and over the sacrum and often passed down the front of the left thigh, never the right. She had suffered from leucorrhœa, but never more severely at any one time than another, and there had never been smarting on urination. Bimanually the uterus was found of normal size, but fixed between two elastic masses, one on each side of the pelvis, the one on the left being much the largest. Her husband strongly objected to the removal of more than one ovary and tube if it could possibly be avoided. Operation was performed on May 6th, the patient being in the Trendelenburg position. A median abdominal incision was made. The *omentum* was lightly adherent to the uterus and left Fallopian tube and separation was easily carried out without any necessity for ligature. The left tube was coiled inwards and downward was con-
verted into a pus sac. The tube reddened,
and occluded. The whole mass was ouch and
one portion yielded during separation, giving exit to a thin brownish fluid which was caught upon sponges which had been packed in behind. After removal the opposite tube was inspected. It was swollen and occluded. The ovary, however, appeared to be healthy and, respecting the husband's wishes, they were *both left.* Recovery was rapid and uneventful and up to the present, six years after, no further trouble had been experienced from the very doubtful tube which was left behind.

CASE 13.—W, 84. Mrs. ——, aged 31 years, was admitted on May 6th, 1898. She had had no children. She had had *menorrhagia* for three periods followed by offensive purulent vaginal discharge. There were pain all over the *abdomen* and tenderness on pressure over the left ovary, together with some gradual abdominal enlargement. *Colotomy* was performed with the patient in the Trendelenburg position. The omentum was adherent to the uterus and *left tube.* The left tube and ovary were converted [illegible] sac and were removed. The right [illegible] ded; this was not removed. The [illegible] Recovery ensued and the patient [illegible]

CASE 14.—I, 172. Mrs. ——, aged 33 years, was admitted on Oct. 23rd, 1898. She had been married 11 years; she had had no children or miscarriages. The menses, which had commenced at 13 years of age, had been always regular. The flow had always been free, lasting for from five to six days. Before marriage black clots were often seen. Since marriage these as well as "lumps of flesh" were noticed. Before marriage there was sacral pain, not so much since. With the period there had always been pain at first, which was relieved by the flow. For the last eight years the pain had been more severe in front in the hypogastrium, at first mainly on the right side, but during the last few months this had changed more to the left side. For the last few months the amount lost had been rather less until the last period which commenced on Oct. 18th; this had been much more copious than usual. There had been three occasions on which the loss amounted to actual flooding [illegible] broad ligaments. The diagnosis made was that of uterine myoma with possibly pyosalpinx or broad ligament outgrowths of the myoma. Operation [illegible] ned on Oct. 27th [illegible] arteries [illegible] ndelen- [illegible]. The [illegible] inx on [illegible] ended, [illegible] The [illegible] order to gain room. The left ovary and tube were then enucleated from very firm adhe[illegible] the right side the tube was [illegible] to close the pe[illegible] abdominal wall was then entirely closed. A hypodermic injection of strychnine was required during the operation. There was very marked shock. Convalescence was slow but ultimately the patient recovered completely.

CASE 15.—S, 109. Mrs. ——, aged 4[illegible] was admitted on April 3rd, 1899. S[illegible] The only child was born 21 years ago. [illegible] The menses had commenced at 18 ye[illegible] to the birth of her child, throughout lactation, and since. The child lived for six years and died from phthisis. The labour was a lingering one but otherwise it was normal. She dated her ill-health from this confinement. She had been losing flesh for over three years. Two years before she began to feel worse and noticed a painful lump in the right iliac fossa. From this time there had been constant heaving and regurgitation of blood. Vagino-bimanual examination detected a rounded mass of the size of an orange in the [illegible] egion, which under chloroform [illegible] right uterine cornu, whilst th[illegible] above Poupart's ligament and [illegible] ment [illegible]. On [illegible] position, the [illegible] man line. The omentum was found [illegible] the pelvis and to the right Fallopian [illegible] voluted mass, with a surface which [illegible] intestine, situated above and to the [illegible] pelvic brim and the peritoneum [illegible] tend into Douglas's pouch, to it [illegible]. On attempting to peel off the [illegible] hough some opening in the tube [illegible] probably not all, of this was caught by sponges; the tube was enucleated as [illegible] abdomen was washed out by saline [illegible]

[illegible] omewhat fixed [illegible] nuous with the [illegible] t a polypus had [illegible] previously. A [illegible] de and vaginal [illegible] l on Sept. 19th [illegible] method was performed on the [illegible] ring Douglas's pouch, owing to [illegible] herefore separated in front and [illegible] plastic [illegible] in the [illegible] was united and gauze was placed in ocum between the divided [illegible] ents. Some slough[illegible] y kept in check by [illegible] tient recovered and [illegible] 9.

[illegible] on Jan. 24th, 1900 [illegible] no children or mis[illegible] riage. Her husband [illegible] as usually perfectly [illegible] between the periods. She had never had any other discharge. Her present illness [illegible] with sudden pain in the right iliac [illegible] The pain was located by her in the [illegible] y's point. There was no diarrhœa or [illegible] ous health, she said, was always good. [illegible] the patient was found to be a stout woman with a healthy colour. She lay on her back with both knees drawn up. The abdomen was irregularly distended by a firm rounded mass which extended from the right inguinal region to beyond the umbilicus and across the median line. This was dull on percussion from Poupart's ligament upwards. It was very tender on pressure. Per vaginam its lower surface [illegible] it did not bulge in [illegible] the Trendelenburg [illegible] from the pubes to [illegible] omentum was found [illegible] the left half of the [illegible] attempt was made to [illegible] and to bring it out of [illegible] rous pus spurted out [illegible] On the right [illegible] other was another [illegible]; this also was [illegible] separate. After [illegible] ttached to the [illegible] The abdominal [illegible] ube was left in the [illegible] that some of the pus from the first mass might have soiled the wound surfaces, this was removed on the third day. It was doubtful whether [illegible]

[illegible] in size. [illegible] posterior [illegible] from which [illegible] 's was packed [illegible] which before operation was [illegible] ot again rise above normal. The [illegible] irrigation was used daily. She [illegible] on Jan. 31st.

CASE 18.—Mrs. ——, aged 44 years, was admitted on Sept. 9th, 1902. She had been in perfect health until her marriage. Soon after marriage she complained of vaginal discharge with smarting on urination. Since her marriage she had never been well [illegible] the la[illegible] The o[illegible] to be [illegible] ing in [illegible] The small intestine was found adherent all over the pelvic floor. The abdominal wound was closed. The patient was again placed in the lithotomy position and the uterus was removed by Landau's method. It contained two small fibroids. On opening the peritoneum several ounces of foul pus escaped, the main amount on opening the utero-vesical space. After irrigation three rubber drain tubes were placed and packed around with gauze. The patient was greatly collapsed and died the next day. At the post-mortem examination foul pus was found in the pelvis. Pus was also found between the duodenum and the common bile duct, between the superior surface of the liver and the diaphragm, and in a pocket formed by adhesions in the right iliac fossa.

[illegible] Feb. 12th, 1903. [illegible] sion. It recurr[illegible] operation was performed on April 11th. The patient being placed in the Trendelenburg position a median abdominal section was made. The omentum was found strongly adherent to the left Fallopian tube which was swollen, closed, and [illegible] adherent to some of the [illegible] The whole mass was so [illegible] d to be begun by division [illegible] tube removed by dissection outwards. When this was removed the right tube was found equally inflamed and convoluted but not so swollen. The right ovary was becoming cystic; both were removed. Many and tough adhesions existed in Douglas's pouch between the uterine fundus, the tubes, and the posterior pelvic peritoneum. The abdominal wall was closed without drainage by tied suture. Recovery was uninterrupted.

CASE 20.—Mrs. ——, aged 32 years, was admitted on March 31st, 1903. On admission she was very ill and but little history could be obtained except that she had been very feverish for over 14 days. She complained chiefly of great pain in the hypogastrium and over the sacrum, passing down both legs. There was also pain on urination. The temperature on admission was 101° F., reaching 103° before operation. The pulse was 112 and the respirations were 44. Bimanual examination showed a large fixed uterus which was pushed over towards the l [illegible] a firm, extremely tender mass attached to, [illegible] it viscus, in the position of the right Fallopian tube; this did not [illegible] were no pulsating vessels in either [illegible] on April 2nd, the patient being [illegible] medium incision was made. The patient had passed urine before coming into the theatre but the bladder was found still distended and consequently carried upwards into the line of division. A catheter was passed and more than a pint of urine was drawn off. After this the bladder sank to its normal position. The omentum was found adherent to the greatly swollen uterus and on separating one of the adhesions some pus escaped. The pus appeared to come from an abscess in the uterine wall. Both tubes were tensely swollen, reddened, and œdematous. On the right, the tube was separated from the pelvic brim, to which it was firmly adherent, and a swollen, multilocularly cystic ovary was brought up. On separating the tube the bladder, which was intimately adherent to it, was opened for about a quarter of an inch and some clear urine escaped; as sponges had been previously packed into Douglas's pouch however, probably no harm was done. The opening was at once closed. The uterus being evidently as thoroughly infected as the tubes, the whole was removed in the American manner, except that the cervix was also taken away, the vagina was opened, and the left tube and ovary were removed from below upwards. The ends of all ligatures were drawn down into the vagina on each side of a roll of gauze and the pelvic peritoneum was partially united over it. By this time, in spite of transfusion and hypodermic injections of strychnine, there were signs of great collapse. The abdominal wall was closed entirely by through-and-through sutures. Transfusion was repeated twice to the extent of two and a half pints each time subcutaneously during the next 24 hours. The strychnine injections were also repeated. A catheter was left permanently in the bladder. Transfusion was again repeated on the 3rd and 4th. There were extreme restlessness and persistent diarrhœa from the second day, flatus being passed during the first night after one dose—three grammes—of calomel. The temperature reached 104° on the third day. The pulse was 140 and the respirations were 30, the latter being of the Cheyne-Stokes type. On the fourth day she was evidently septicæmic; on the fifth day the temperature sank to 99·8°. The pulse was 120 and the respirations were 52. The diarrhœa still continued, however, and she died early on the sixth morning. At the post-mortem examination pus was found in the pelvis, the right side of which was sloughing. Both pleuræ and the pericardium contained several ounces of brownish serum. Both lungs were congested, bluish, and collapsed. The abdominal wall had yielded and at the upper part of the wound the small intestine was close below and adherent to the skin. The small intestine lay in transverse rows which were all adherent to the anterior wall, the lower coils to the pelvis. One coil was reddened and more firmly fixed to the pelvis on the right side. On separating the coils in the hypogastrium some turbid serum escaped from between them. The bladder was watertight and stood a full pressure of water from the main. The gauze vaginal drain had evidently not been efficient in clearing the pelvis.

CASE 21.—Mrs. ——, aged 32 years, was admitted on Sept. 1st, 1903. She had had no children or miscarriages and had been married nine years. The menses began at between 17 and 18 years of age and were always painless, but never very free. She was always regular whilst they lasted but since her marriage the amounts lost gradually diminished and for the last few years she had had amenorrhœa. Her health was perfect until her marriage and she remembered a sharp attack of pain and smarting on micturition soon after that event. Five weeks before admission she had a sudden attack of severe pain in the hypogastrium, accompanied by vomiting, which had continued more or less up to the time of her entrance into the hospital. At that time she complained chiefly of pain and swelling in the hypogastrium with some difficulty in urination. The abdomen contained an elastic defined swelling in the hypogastrium, which extended into both iliac fossæ and was very tender. The breasts were similar to those of a virgin. The cervix was carried high up. In front, between this and the bladder, was a soft elastic mass which bulged slightly into the vagina. No fluctuation could be felt in it and it was very tender to the touch. Operation was performed on Sept. 2nd, the patient being in the lithotomy position. Posterior colpotomy revealed a small apparently unaltered uterus with a large mass above and in front of it. An incision was then made in front of the cervix and over the projection noted. This was deepened for about one inch with no result, but a forceps pushed onwards in front of the uterus entered a cavity which on opening the blades of the instrument discharged several ounces of offensive grumous pus. The opening was widened, the cavity was washed out, and two drainage-tubes were introduced. These tubes were kept in position for nearly three weeks, as it was found that when they were removed the bladder acted as a valve, shutting the opening, and the cavity was refilled. Through these daily irrigation was done. At last they were practically pushed out by the contraction of the space. The temperature, which was 102·6° F. before operation, steadily decreased to normal and the patient went home on Oct. 3rd, no thickening of any kind being detectable on her leaving the hospital.

CASE 22.—Mrs. ——, aged 33 years, was admitted on Dec. 26th, 1903. She had had no children or miscarriages. Her sexual history had evidently been irregular. She, however, dated the commencement of her ill-health to the time after marriage. 15 years ago, however, she was in another hospital for flooding with tenesmus and some vaginal discharge. In August, 1902, she said that she had "inflammation of the womb." She was a thin, worn-looking woman, evidently in great pain, complaining of purulent vaginal discharge and [illegible] hypogastrium. The uterus was found to be fix [illegible] n elastic, rounded, fixed mass by its left side. [illegible] on Dec. 31st, the patient being in the Trendelenburg position. A median abdominal incision was made. The omentum was firmly adherent to the small intestine, uterus, and to the uterine end of the left Fallopian tube. When this was separated a loop of small intestine was found adherent to the posterior wall of the uterus and the left Fallopian tube. In freeing this, which had to be done by the scissors at the expense of the tube, some cheesy pus escaped from the latter. The bladder was separated off in front and the uterus with both tubes and ovaries, which were all greatly swollen and contained pus, were removed. The left tube was greatly elongated and passed down behind the broad ligament to the bottom of Douglas's pouch, to which it was firmly fixed. The right tube was short but closed and swollen. Its inner lining was inflamed and coated with thin clot. The ovary on this side was slightly cystic, some of the cysts containing pus. In the right broad ligament was an ulcerated opening leading into a small cavity, from which some foul granulation material was scraped away. An opening was made from this cavity into the vagina and a gauze drain was drawn through into that canal. The ligatures were all drawn through into the vagina and between them a gauze drain, the upper end of which was left just flush with the peritoneal surface. On the posterior peritoneum were some remains of what looked like part of the wall of a pus cavity. This was snipped away with scissors. When all was done there was left a very ragged-looking Douglas's pouch. No attempt was made to close the pelvic peritoneum. The abdominal wall was closed. The operation lasted two and a half hours. Transfusion was required on the table. For about two hours there was a great amount of collapse, restlessness, and abdominal pain. The last two were relieved by the hypodermic injection of morphine. Transfusion of two pints was again performed five hours later, not because of shock, but with the idea of diluting and more quickly removing any toxin formed. Nutrient enemata with brandy were given every four hours. There was some hæmorrhage from the vagina during the first 12 hours. The vaginal plug was removed on the fourth day. The patient rallied well and recovered completely, returning home on Feb. 16th, six weeks after the operation.

CASE 23.—Mrs. ——, aged 32 years, was admitted on June 2nd, 1903. She had had four children, the youngest being five years old. Her husband had been dead four years. She had had no miscarriages. All the confinements were normal except the last but one, nine years ago, when she was attended by a midwife, who had some difficulty in the removal of the placenta. All the children were healthy. Since her husband's death she had gone out charing in all weathers. Menstruation had always been regular except during pregnancies and lactation. The periods recurred always three days less than a month. There was always some little pain about the second day, the periods always lasted three or four days, and the amount was always moderate. One period appeared between the [illegible] ation, and this was entirely painless. [illegible] a bicycle and "kencked" herself, fe [illegible] but in a day or two she felt well again. [illegible] ll aching pain was first felt over the umbilical region; there was never any sacral pain. She was poulticed for three days and kept in bed, with the result that this pain disappeared, but it was succeeded by a gnawing sharp pain in the right iliac region. Bimanually the uterus was found enlarged with an elastic tender mass on the right side and behind. There was no tenderness or enlargement detected on pressure over the appendix. Operation was performed on June 15th, the patient being in the Trendelenburg position. A median section was made. On opening the peritoneum the uterus was found to be enlarged, with a large right Fallopian tube, the fimbriæ of which were closed and adherent to the ovary which was transformed into a small multilocular cyst, both being fixed by adhesions to the back of the uterus and the broad ligament. On the left side the Fallopian tube was swollen and its fimbriated extremity was closed. The left ovary was a mere pus sac. Both tubes and ovaries were removed and the abdominal wall was closed. The convalescence was uninterrupted and the patient went home on July 3rd about three weeks after the operation.

Manchester.

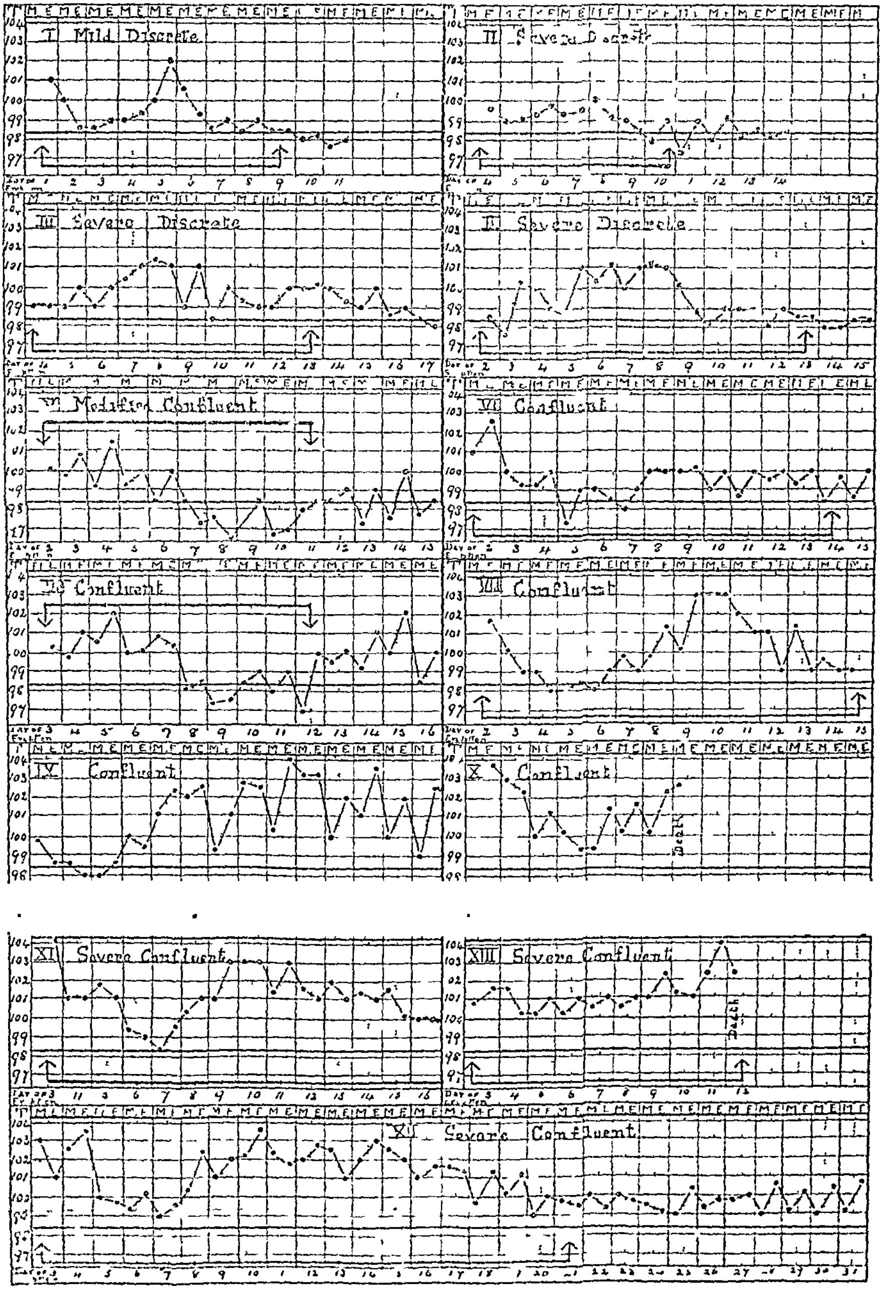
THE RED LIGHT TREATMENT OF SMALL-POX.

BY T. F. RICKETTS, M.D., M.R.C.P. LOND.,
MEDICAL SUPERINTENDENT OF THE SMALL-POX HOSPITALS OF THE METROPOLITAN ASYLUMS BOARD;

AND

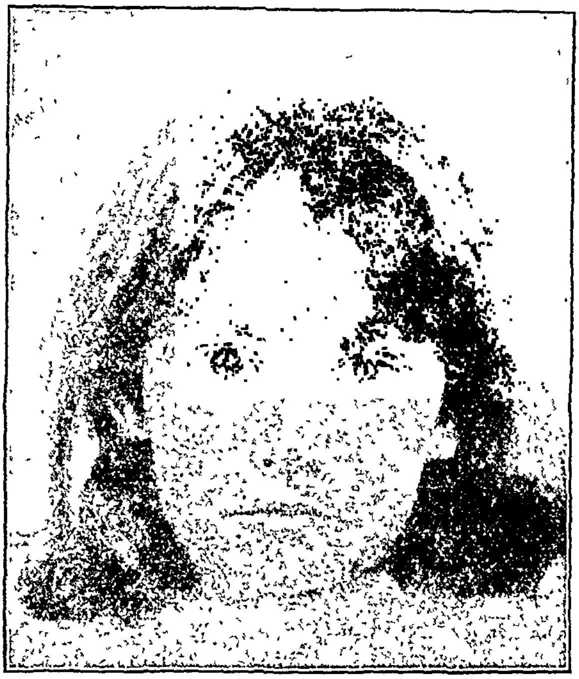
J. B. BYLES, M.B., B.C. CANTAB., F.R.C.S. ENG.,
ASSISTANT MEDICAL OFFICER AT THE JOYCE GREEN HOSPITAL.

IN THE LANCET of July 30th, p. 287, an article was communicated by us on the red light treatment of small-pox. The article appeared without the temperature charts and photographs which were intended to illustrate it, but these charts and reproductions are now published separately as they furnish forcible evidence in favour of our contentions. The 13 temperature charts illustrate the 13 cases treated by us in red light and the numbers correspond with those in the tabular list of cases contained in the article, to which we refer the reader. The charts illustrate the point that treatment by red light did not prevent the fever of suppuration which was absent in only one case of modified small-pox (Case 5). It is to be remembered that as treatment in red light is claimed to prevent the fever of suppuration only no account is to be taken of pyrexia occurring before the fifth day of efflorescence. The duration of the treatment in red light is indicated on the charts by vertical arrows connected by a horizontal line. Of the four photographs reproduced,



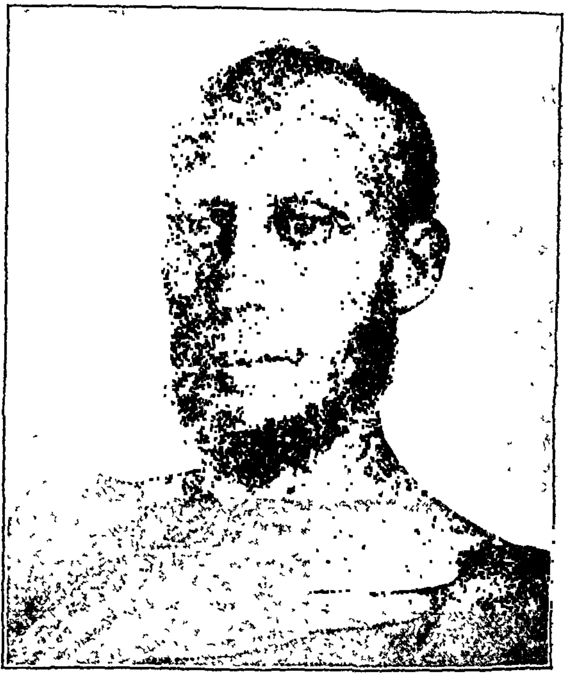
Temperature charts of 13 small pox cases treated by red light.

FIG. 1.



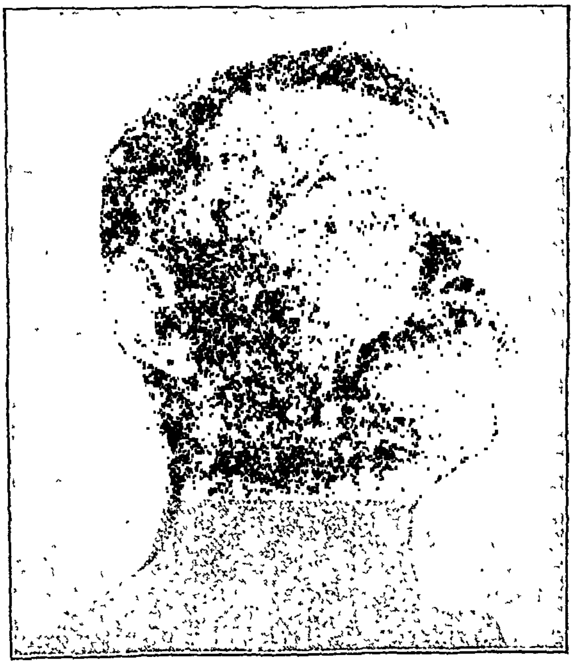
Case 8. Confluent small-pox. Vaccinated at time of invasion only. Convalescent after red light. Shows bad scarring.

FIG. 2.



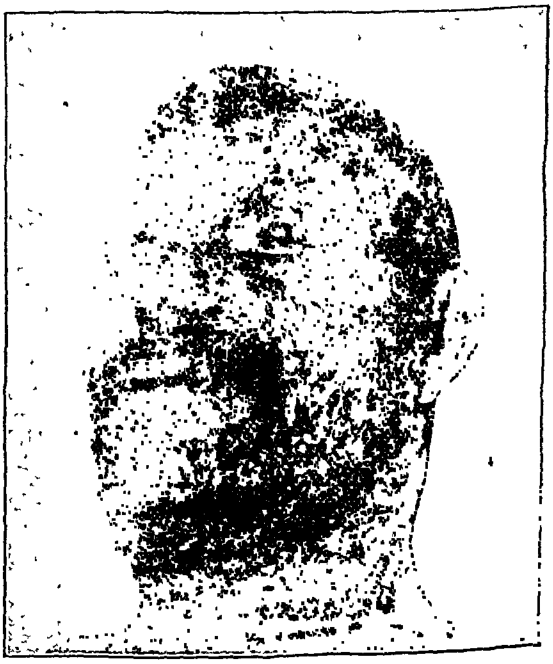
Case 11. Severe confluent small-pox. Vaccination doubtful. Convalescent after red light. Severe scarring and alopecia.

FIG. 3.



Case 12. Severe confluent small-pox. Vaccinated. Photographed before red light.

FIG. 4.



Case 12. Photographed during red light treatment in late stage of suppuration.

two (Cases 8 and 11) were taken during convalescence from patients who (contrary to the claims made for the treatment) were badly scarred In one of these cases (Case 11) there was also considerable alopecia Some other of the patients treated were scarred but it was not thought necessary to produce photographic records in further illustration of the point It was curious in regard to Case 8 that the child was admitted with her sister and that both had been vaccinated and developed small pox on the same days The two children had attacks apparently of comparable severity *Yet the child who was not treated in the red ward had a* modified eruption and recovered without scars, while her less fortunate sister, as may be seen by the illustration, was badly marked Two photographs of Case 12 are reproduced The first of these was taken before the patient entered the red ward and indicates the very early stage which the eruption had then attained The second was taken late in the pustular stage, on the ninth day of efflorescence, the patient being temporarily removed from the red ward for the purpose The two photographs therefore illustrate the fact *that although the treatment was begun early it wholly failed* (as in other cases) to prevent or to check the normal development of the lesions.

INSPECTION OF THE ANTRUM OF HIGHMORE.

BY A BROWN KELLY, M D , D SC GLASG ,
SURGEON FOR DISEASES OF THE THROAT AND NOSE, VICTORIA INFIRMARY, GLASGOW

THE methods of diagnosing disease of the antrum at present in vogue give information only as to the fluid contents of the cavity but none as to the condition of the lining membrane if we except transillumination which occasionally indicates this to be more or less thickened The diagnosis is therefore based solely on the discharge and our management of antral suppuration may be compared to the treatment of otorrhœa without examination of the ear In dealing with the *antrum questions frequently* arise which make the inspection of its lining membrane desirable Thus there may be doubt as to whether pus is forming in the antrum or merely collecting there, whether the suppuration is limited to a small area or involves the whole lining membrane, and whether the changes in the lining membrane are slight and will probably yield to mild measures, or considerable and demand a radical operation Further, how else than by inspection are we to gain a true knowledge of antral affections? Is it not something of a reproach that although cysts and polypi are present not infrequently, as proved by post mortem examinations, we have no signs or symptoms by which to diagnose them during life? Lastly, are our remedial measures to remain as limited as heretofore? If we fail to check a discharge by simple means—e g , syringing, or insufflating powders—is our sole alternative method to be the radical operation entailing general anæsthesia and confinement indoors for at least a week? Considerations such as *these led me to seek an easy mode of gaining* access to the antrum, and having devised this to attempt the treatment of the diseased lining membrane by methods which had proved of utility in similar conditions of the mucous membrane of the nose and ear

The method of opening the antrum is as follows The gingivo labial fold beneath the canine fossa is painted with 20 per cent solution of cocaine. From four to six cubic millimetres of 10 per cent solution of cocaine are injected at two or three points in the anæsthetised area into the soft tissues over the canine fossa After three or four minutes have elapsed the zygomatic alveolar ridge is noted and commencing just in front of it an incision is carried forward along the gingivo labial fold for about from one and a half to two centimetres The facial wall of the superior maxilla is now exposed by pushing aside the investing soft tissues *with a raspatory The sharp trocar (Fig 1) is applied to* the bony surface at a point about five millimetres in front of the zygomatic alveolar ridge and about the same distance above the incision in the mucous membrane Having bored a passage large enough to admit the end of the blunt pointed trocar (Fig 2) the latter is used to make the full sized opening. By completing the operation with a blunt pointed instrument the danger of injuring the opposite wall is averted The trocars should be directed backwards, upwards, *and slightly inwards The operation is simple, often* painless, although occasionally somewhat so when boring through the bone, can be quickly accomplished, and has in my experience but one drawback—namely, the necessity for the submucous injection of cocaine I have tried eucaine in 20 per cent solution but sensation was not satisfactorily abolished

FIG. 1.

FIG 2

The landmark referred to, the zygomatic alveolar ridge, descends from the malar process to the alveolar border above the first molar I have recommended that the incision should terminate posteriorly just in front of this ridge, for when carried further back a small arterial twig is cut, if this escapes the bleeding is unimportant and no special measures for its control are necessary In exposing the canine fossa one is not likely to pass so high as the infra-orbital foramen, still it should be kept in mind The advantages of using large trocars to make an opening into the

r wound with greater
less discomfort to the
of chiselling

To obtain a good view of the antrum a speculum is necessary A large sized ear speculum or Zaufal's naso pharyngeal speculum cut down serves the purpose. An instrument such as that depicted (Fig 3) is, however, most satisfactory It resembles a large, elongated aural speculum of circular calibre with bevelled end The last provision facilitates its introduction and when in use gives a more extensive field of view and allows of the freer manipulation of instruments in the cavity An extra long speculum (Fig. 4) is useful at times—e g , when œdema of the lining membrane more or less occludes the lumen the opposing surfaces may be pushed apart by the instrument and the deeper regions inspected. To introduce the speculum the left forefinger is used to raise the lip and so cause the wound to gape The speculum is then passed in gently. If any difficulty is encountered it is best overcome by looking through the speculum, mopping away the blood if necessary, and then pushing aside the soft tissues with a probe or avoiding the bony ridge of the opening by altering the direction of the instrument

FIG 3

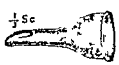


FIG 4.

On introducing the speculum the posterior part of the antrum directly meets the view By inclining the instrument in various directions and turning the bevelled part towards the region to be examined the lining membrane of the greater part of the cavity may be minutely inspected. The parts of which a view is unobtainable are the anterior wall and those portions of the other walls immediately adjacent, especially the roof The ostium maxillare is usually not seen owing to the inner wall being viewed in perspective, but its position is easily determined by a *right* angled probe under control of the eye If the artificial opening were bored further outwards—e g , over the zygomatic alveolar ridge—instead of in the canine fossa the ostium would be visible and a better view of the inner wall obtainable, but for general purposes the route already recommended is probably best, and it has the further advantages that here the bone is thinnest and the speculum is most easily introduced

Immediately after the operation having syringed the antrum if necessary, a look may be taken at its lining membrane The detailed examination is best postponed, however, till the following day, the wound meantime being loosely packed with iodoform gauze. On the first night there may be some pain but it is usually insignificant. Slight swelling of the cheek may be present after the operation or may develop more markedly on the following day or later, especially if the patient has been exposed to cold, and may last from a couple of days to a week. It is sometimes considerable, extending to the lower eyelid and causing marked disfigurement, but it is associated with comparatively little discomfort. At the patient's second visit the gauze is removed, the antrum is syringed, and the lining membrane is thoroughly examined by means of a strong, bright light reflected through the speculum.

Occasionally the patient complains of the speculum causing pain. This may be avoided in a large measure by painting the parts with cocaine and using a smaller speculum. The tenderness is usually referred to the lower bony edge of the opening on which the instrument presses. As long as it is desired to have access to the antrum the wound in the soft tissues must be kept open by means of packing. After this is discontinued it rapidly narrows and closes. Over 40 antra have been opened and inspected in the manner described. The various affections met with, the methods of treatment employed, and the results obtained are briefly recorded below.

Antra in which the lining membrane was normal or but slightly changed.—In several of these cases suppuration was apparently going on in the antrum, for pus was being regularly washed out by syringing through an opening made in the alveolus. On inspecting the cavity, however, the lining membrane seemed normal or but slightly thickened on the floor. In order to exclude the antrum as the seat of the suppuration it was packed with gauze and as the discharge of pus from the nose was undiminished clear evidence was thus afforded that the antrum was merely a reservoir for pus draining into it from the frontal sinus or ethmoidal cells. This method is therefore capable of yielding valuable information as to the source of pus issuing from the anterior part of the middle meatus. In one of the cases of this group the patient suffered from nasal polypi, the recurrence of which could not be controlled, and in another there was persistent and excessive swelling of the inferior turbinates without manifest cause. The antra in both of these cases were suspected on account of other signs and symptoms, but wrongly as inspection proved. In those cases in which the antrum was opened but the lining membrane found normal the wound was immediately allowed to close. A couple of stitches to keep the soft tissues together and prevent the entrance of food would perhaps have been advisable but none were used, the patient merely placing a small pad of gauze in the gingivo-labial fold over the wound while eating. In all of the cases healing took place without any untoward effect.

General thickening of the antral lining membrane.—The majority of the patients whose antra were inspected suffered from chronic antral suppuration and in most of these cases the appearances presented by the diseased lining membrane varied but little and consisted in a general thickening. The surface of the membrane was pale and smooth; ulceration was observed in no instance. The degree of thickening was not uniform; without exception it was greatest on the floor and least in the upper part of the cavity, a fact which emphasises the irritant action of pus lying in the antrum. In one case, in which the antrum had been previously syringed from the alveolus for several months, a nipple-shaped proliferation a quarter of an inch long projected from the floor, the passage for the cannula running through the centre of it. Besides being thickened the lining membrane was sometimes swollen so that adjacent walls, instead of passing into one another imperceptibly, met at an angle, and the point of the probe was lost sight of between the folds. A tooth was found lying loose in the cavity in two instances; one had been forced up in an attempt to extract it. In cases in which the suppuration might possibly have been of dental origin the floor of the antrum was carefully examined but without ever discovering the mouth of a sinus or other indication to support this view.

The antral suppuration in several of the cases presenting the above appearance was associated with nasal polypi or frontal sinus suppuration, or both, and in one instance with fœtid atrophic rhinitis. In these cases of chronic suppuration in the antrum attempts were made to check the discharge, either by modifying the diseased mucous membrane or by destroying it and encouraging the growth of a new lining membrane. Various medicaments were tried. Antiseptic powders were insufflated, boric acid, iodoform, iodol, airol, aristol, and europhen being in turn applied, but all without appreciable benefit. Packing the cavity with boric acid increased the discharge; with iodoform it was somewhat diminished. Liquid applications of an astringent or caustic nature—e.g., chloride of zinc, silver nitrate, or carbolic acid—were also repeatedly employed but proved inefficient. Of all medicaments tried chromic acid fused on the end of a probe was found to be the most useful. It had the additional advantage of being easily applied. Experience showed that it was inadvisable to cauterise more than half of the antral surface at a sitting. Where thickening was marked, as on the floor in many cases, the bead might be firmly rubbed over the lining membrane, but caution was necessary where the membrane was less thick, otherwise considerable pain might be suffered afterwards. In my later cases I found it best to cauterise lightly twice or thrice at intervals of a few days and to syringe out the cavity after each application with a solution of bicarbonate of soda. Usually on the second day following the cauterisation the surface of the mucous membrane that had been treated presented a dirty grey appearance and was found to consist of necrosed tissue which could be wiped or picked away more or less completely. Perfect healing required from two to three weeks and the membrane was then smooth, grey, and much thinner than before.

By means of chromic acid used in the manner described I was able to get the lining membrane into a healthier state and to diminish suppuration but unfortunately not to check it completely. The treatment was continued, as a rule, for not longer than three or four weeks and possibly if it had been persevered with cures might have been obtained. The difficulty, however, was to keep the opening free owing to the soft tissues constantly encroaching upon it. If this tendency to closure of the wound could be overcome without causing discomfort to the patient and easy access to the cavity maintained, excellent results might, I believe, be obtained. Curetting was also tried. This to be effective must secure the removal of the entire diseased lining membrane. I have found that it is not possible to operate thus without severe pain, even if only a small area which previously had been thoroughly painted with a 20 per cent. solution of cocaine is treated at a time. After a few trials, therefore, I abandoned the idea of curetting without a general anæsthetic.

Œdema and thickening of the antral lining membrane.—In a few cases œdema was the most striking change presented by the antral lining membrane. On introducing the speculum little or no lumen was found, the inner and outer walls of the cavity being swollen to such a degree as to meet. These swellings had a dull grey aspect and were yielding, elastic, and somewhat fluctuant, giving one the impression of a bag partly filled with fluid. On aspiration, however, no fluid was obtained and on incision there was no apparent leaking or shrinking. If the cavity were loosely packed with gauze the lumen on the following day was found to be greater and the œdema of the lining membrane was correspondingly less; and if the packing were repeated for several days the swelling gradually disappeared and less or more thickening alone remained. In the most marked cases of œdema of the antral lining membrane the discharge was usually of a muco-purulent nature and the prominent feature in the nasal fossæ was polypoid rhinitis, or polypi, sometimes of an obstinately recurrent character. After the œdema had subsided the lining membrane was treated with chromic acid in the manner already described. A decided opinion cannot be expressed as to the ultimate effect, but the impression gained was that the abnormal secretion from the antrum was diminished and that the nasal condition was improved.

Polypi and polypoid degeneration of the antral lining membrane.—Polypi were found in one case and polypoid degeneration in three cases. The case of polypi in the antrum was that of a young woman who suffered from abundant muco-purulent nasal discharge and a polypoid condition of the inferior and middle turbinates. On opening her left antrum a white, soft, cheesy material was encountered. After washing this out the greater part of the lining membrane was seen to be smooth, thin, and pink. A pedunculated multilobular polypus of about the size of a bean hung from the inner part of the roof and a similar growth but double its size sprang from the floor. In the right antrum polypi were found attached to the inner, outer, and anterior walls and to the floor. All these growths resembled nasal polypi in appearance. In the cases of polypoid degeneration either flat, sessile bodies, having the grey gelatinous look of polypi were situated individually on various parts of the antral lining membrane or were closely packed together All three patients had antral suppuration, although the discharge of pus was not abundant and two suffered in addition from recurrent nasal polypi The pedunculated polypi were snared and the sessile ones were reduced by cauterisation with chromic acid The antral affection was cured in one case and improved in the others, *the nasal condition was also ameliorated*

Cysts of the antral lining membrane —Cysts were found in the antrum in one case The patient was a young woman who had muco purulent rhinitis probably of a strumous nature with a tendency to recurrent polypoid proliferations of the middle turbinates On examining her left antrum the cavity was found filled with very tough mucus after the removal of which a large white cyst was seen close to the opening On incising it scanty pus and a quantity of thick mucus escaped Other cysts previously concealed were *now disclosed One was situated on the floor*, *a small flat* one sprang from the inner wall a moderate sized one hung from the roof, and the sac of a collapsed one was present on the outer wall The cysts were incised and chromic acid was applied to their lining membranes where accessible Shortly afterwards there was marked improvement in the nasal condition, but as both fossæ participated it is doubtful whether this can be attributed to the treatment of one antrum, the other having not been opened

Inspection of the antrum has revealed to me some highly *interesting conditions* but *as regards treatment I have no* sensational results to chronicle The ease and safety with which the method can be carried out justify its adoption as a diagnostic procedure On the other hand the results which I have obtained by the direct treatment of antral disease as described in this paper warrant only its reserved recommendation

THE VISUAL FIELDS IN TOBACCO AMBLYOPIA[1]

By N BISHOP HARMAN M A, M B Cantab
F R C S Eng

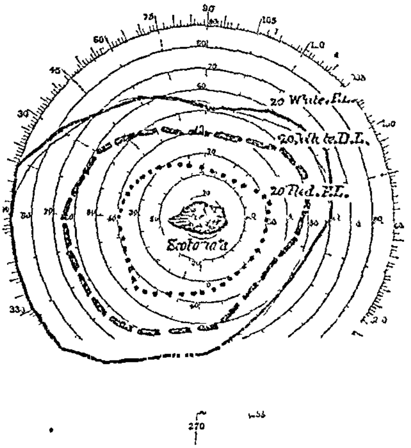
OPHTHALMIC SURGEON TO THE BELGRAVE HOSPITAL FOR CHILDREN
CHIEF CLINICAL ASSISTANT TO THE ROYAL LONDON OPHTHALMIC
HOSPITAL AND CLINICAL ASSISTANT TO THE OPHTHALMIC
DEPARTMENT OF THE MIDDLESEX HOSPITAL

We are accustomed to summarise the subjective symptoms of tobacco amblyopia as involving a loss of visual acuity the result of a central scotoma partial or complete, in the early stage simply a colour scotoma, later and in bad cases the scotoma may become absolute indicated by a loss of perception for small white objects centrally But—and this is a point often insisted upon—the outer limits of the visual fields are not contracted they extend to their normal bounds In short, there appears on the case paper 'tobacco amblyopia central scotoma for colours fields for white full Then there is the cardinal symptom of Arlt's original description—nyctalopia

The cases which I have investigated indicate that the
commonly received view of t
i e the vision is not affected
be diminished peripherally wh
used and perhaps also over the whole field At the same time the fields show a reasonable explanation for the frequently repeated assertion of patients that they see better in the dim light than in full daylight

The perimeter room at the Royal London Ophthalmic Hospital is a small room lined with glazed white brick on three sides, the fourth side is almost filled with windows, the large window space and the glazed bricks make the illumination of the room uniformly good The windows can be covered by black blinds but the room is not absolutely darkened as light passes in between the white window frames and the edges of the blinds and is diffused by reflection from the walls into an uniformly dim light With the room fully lighted I can read J 1 at a distance of about 1 2 millimetres from the central spot of the perimeter, when the blinds are drawn I can just read the same type when my chin is resting on the chin plate of the perimeter It follows that the light of the room has been reduced to about one tenth of its normal brilliance by drawing down the blinds

The method I have used in examining the visual condition of patients differs only from the usual procedures in that I have taken the fields for white objects twice first in the room fully lighted and again when dimly lighted with the *blinds drawn The visual acuity of the eyes is noted*, then the fields are taken for white and red with full illumination, and last the fields for white in the dim light I am well aware how easily a little unconscious bias may make a great difference in taking such measurements as those of fields I have therefore endeavoured to eliminate the personal equation by taking the measurements in as mechanical fashion as possible, thus by using a different pricker the fields for white in full and dim light can be taken on the same chart without the necessity of looking at the chart whilst the measurements are being *taken and in repeating* the examination of cases on dates subsequently to their first examination the earlier charts are not referred to



Left field of a male aged 50 years Vision failing from two to three months has difficulty in distinguishing a sixpence from a half sovereign R V = [illegible] L V = [illegible] No error of refraction other than presbyopia Smokes from

20 × 20 mm red object full in light

I have examined in this fashion all cases that have attended one of the cliniques at Moorfields during the past eight months to the number of 25 and by way of contrast there have been taken in the same manner the fields of some half dozen apparently healthy subjects smokers and non smokers In the healthy subjects the fields (examined with a 20 × 20 millimetre white object) were full both when the *room was fully illuminated* and when the blinds were drawn down—that is to say the diminution of the light to one tenth of its usual brilliance did not affect the perception of a 20 millimetre white object moving about the perimeter arc In the subjects of tobacco amblyopia of moderate severity the examination of the field for a 20 millimetre white object with the usual full illumination shows that the outer limits of vision are normal, and by searching the region of the macula with small white objects (one or two millimetres) there is only occasionally any indication of defect In making this central examination I found it advisable to correct any marked error of *refraction* When, however the light is diminished by drawing the window blinds a re examination of the fields shows a different result.

[1] Demonstrated in the museum of the Ophthalmological Section of the British Medical Association Oxford, July 1904.

loosely packed with iodoform gauze. On the first night there may be some pain but it is usually insignificant. Slight swelling of the cheek may be present after the operation or may develop more markedly on the following day or later, especially if the patient has been exposed to cold, and may last from a couple of days to a week. It is sometimes considerable, extending to the lower eyelid and causing marked disfigurement, but it is associated with comparatively little discomfort. At the patient's second visit the gauze is removed, the antrum is syringed, and the lining membrane is thoroughly examined by means of a strong, bright light reflected through the speculum.

Occasionally the patient complains of the speculum causing pain. This may be avoided in a large measure by painting the parts with cocaine and using a smaller speculum. The tenderness is usually referred to the lower bony edge of the opening on which the instrument presses. As long as it is desired to have access to the antrum the wound in the soft tissues must be kept open by means of packing. After this is discontinued it rapidly narrows and closes. Over 40 antra have been opened and inspected in the manner described. The various affections met with, the methods of treatment employed, and the results obtained are briefly recorded below.

Antra in which the lining membrane was normal or but slightly changed.—In several of these cases suppuration was apparently going on in the antrum, for pus was being regularly washed out by syringing through an opening made in the alveolus. On inspecting the cavity, however, the lining membrane seemed normal or but slightly thickened on the floor. In order to exclude the antrum as the seat of the suppuration it was packed with gauze and as the discharge of pus from the nose was undiminished clear evidence was thus afforded that the antrum was merely a reservoir for pus draining into it from the frontal sinus or ethmoidal cells. This method is therefore capable of yielding valuable information as to the source of pus issuing from the anterior part of the middle meatus. In one of the cases of this group the patient suffered from nasal polypi, the recurrence of which could not be controlled, and in another there was persistent and excessive swelling of the inferior turbinates without manifest cause. The antra in both of these cases were suspected on account of other signs and symptoms, but wrongly as inspection proved. In those cases in which the antrum was opened but the lining membrane found normal the wound was immediately allowed to close. A couple of stitches to keep the soft tissues together and prevent the entrance of food would perhaps have been advisable but none were used, the patient merely placing a small pad of gauze in the gingivo-labial fold over the wound while eating. In all of the cases healing took place without any untoward effect.

General thickening of the antral lining membrane.—The majority of the patients whose antra were inspected suffered from chronic antral suppuration and in most of these cases the appearances presented by the diseased lining membrane varied but little and consisted in a general thickening. The surface of the membrane was pale and smooth; ulceration was observed in no instance. The degree of thickening was not uniform; without exception it was greatest on the floor and least in the upper part of the cavity, a fact which emphasises the irritant action of pus lying in the antrum. In one case, in which the antrum had been previously syringed from the alveolus for several months, a nipple-shaped proliferation a quarter of an inch long projected from the floor, the passage for the cannula running through the centre of it. Besides being thickened the lining membrane was sometimes swollen so that adjacent walls, instead of passing into one another imperceptibly, met at an angle, and the point of the probe was lost sight of between the folds. A tooth was found lying loose in the cavity in two instances; one had been forced up in an attempt to extract it. In cases in which the suppuration might possibly have been of dental origin the floor of the antrum was carefully examined but without ever discovering the mouth of a sinus or other indication to support this view.

The antral suppuration in several of the cases presenting the above appearance was associated with nasal polypi or frontal sinus suppuration, or both, and in one instance with fœtid atrophic rhinitis. In these cases of chronic suppuration in the antrum attempts were made to check the discharge, either by modifying the diseased mucous membrane or by destroying it and encouraging the growth of a new lining membrane. Various medicaments were tried. Antiseptic powders were insufflated, boric acid, iodoform, iodol, airol, aristol, and europhen being in turn applied, but all without appreciable benefit. Packing the cavity with boric acid increased the discharge; with iodoform it was somewhat diminished. Liquid applications of an astringent or caustic nature—e.g., chloride of zinc, silver nitrate, or carbolic acid—were also repeatedly employed but proved inefficient. Of all medicaments tried chromic acid fused on the end of a probe was found to be the most useful. It had the additional advantage of being easily applied. Experience showed that it was inadvisable to cauterise more than half of the antral surface at a sitting. Where thickening was marked, as on the floor in many cases, the bead might be firmly rubbed over the lining membrane, but caution was necessary where the membrane was less thick, otherwise considerable pain might be suffered afterwards. In my later cases I found it best to cauterise lightly twice or thrice at intervals of a few days and to syringe out the cavity after each application with a solution of bicarbonate of soda. Usually on the second day following the cauterisation the surface of the mucous membrane that had been treated presented a dirty grey appearance and was found to consist of necrosed tissue which could be wiped or picked away more or less completely. Perfect healing required from two to three weeks and the membrane was then smooth, grey, and much thinner than before.

By means of chromic acid used in the manner described I was able to get the lining membrane into a healthier state and to diminish suppuration but unfortunately not to check it completely. The treatment was continued, as a rule, for not longer than three or four weeks and possibly if it had been persevered with cures might have been obtained. The difficulty, however, was to keep the opening free owing to the soft tissues constantly encroaching upon it. If this tendency to closure of the wound could be overcome without causing discomfort to the patient and easy access to the cavity maintained, excellent results might, I believe, be obtained. Curetting was also tried. This to be effective must secure the removal of the entire diseased lining membrane. I have found that it is not possible to operate thus without severe pain, even if only a small area which previously had been thoroughly painted with a 20 per cent. solution of cocaine is treated at a time. After a few trials, therefore, I abandoned the idea of curetting without a general anæsthetic.

Œdema and thickening of the antral lining membrane.—In a few cases œdema was the most striking change presented by the antral lining membrane. On introducing the speculum little or no lumen was found, the inner and outer walls of the cavity being swollen to such a degree as to meet. These swellings had a dull grey aspect and were yielding, elastic, and somewhat fluctuant, giving one the impression of a bag partly filled with fluid. On aspiration, however, no fluid was obtained and on incision there was no apparent leaking or shrinking. If the cavity were loosely packed with gauze the lumen on the following day was found to be greater and the œdema of the lining membrane was correspondingly less; and if the packing were repeated for several days the swelling gradually disappeared and less or more thickening alone remained. In the most marked cases of œdema of the antral lining membrane the discharge was usually of a muco-purulent nature and the prominent feature in the nasal fossæ was polypoid rhinitis, or polypi, sometimes of an obstinately recurrent character. After the œdema had subsided the lining membrane was treated with chromic acid in the manner already described. A decided opinion cannot be expressed as to the ultimate effect, but the impression gained was that the abnormal secretion from the antrum was diminished and that the nasal condition was improved.

Polypi and polypoid degeneration of the antral lining membrane.—Polypi were found in one case and polypoid degeneration in three cases. The case of polypi in the antrum was that of a young woman who suffered from abundant muco-purulent nasal discharge and a polypoid condition of the inferior and middle turbinates. On opening her left antrum a white, soft, cheesy material was encountered. After washing this out the greater part of the lining membrane was seen to be smooth, thin, and pink. A pedunculated multilobular polypus of about the size of a bean hung from the inner part of the roof and a similar growth but double its size sprang from the floor. In the right antrum polypi were found attached to the inner, outer, and anterior walls and to the floor. All these growths resembled nasal polypi in appearance. In the cases statistics or theories on the causation or prevalence of *measles, enteric fever, and typhus* fever under the last-named single heading The absurdity of such a step would at once be manifest. Classification according to tissue origin *reveals nine* distinct *genera* of malignant new growth, with 13 well marked *species* Or if we include the blastomata, that small and rare class which springs from *embryonic residua and* thus complies with the well known theory of Cohnheim, we have ten genera Each of the above nine owns a different mode of causation, and of every one the exciting cause is accurately known and clearly defined in technical works[5] By overlooking this primary essential of differentiation between lesions of utterly di[illegible] *differing clinical* features the [illegible] ance, materially in its own de[illegible] journalistic fictions, to the frequent charges of ignorance and helplessness *Of what avail are arguments, researches,* or statistical returns which bracket together such distinct varieties as an epithelioma of the tongue or lip and a carcinoma of the mamma? and which in addition commonly designate both as "carcinoma" The former is invariably brought on by continued mechanical friction, the latter follows a train of neurotic antecedents hindering or perverting the *normal physiological* changes of an actively functional organ to the stage of disuse and atrophy The mode of causation in the first instance is patent and obvious, in the latter it *can only* be established by careful examination, by the collocation of sundry examples, and by carefully sifting historical details The nuclei or nuclear fragments of an epithelioma are *with rare exceptions* arrested finally by the adjacent lymph glands, whereas those of a carcinoma, after a merely temporary detention by these organs, pass readily into the blood current and so are carried on to distant parts This indicates a profound distinction between the qualities of the protoplasm in each of the two maladies, now more or less confounded

Then there is what I would regard as a third phase or modification of the malignant cell. The nuclear fragments of the sarcoma corpuscle pass early into the blood and are grafted *as* metastases in distant viscera *But previously* to the *general* blood contamination they do *not* grow within the lymph glands though there can be no doubt that they are conveyed to these organs by the lymph *current. The vague* use of the word "sarcoma" for many species of malignant tumour beside that derived from the connective tissues—it denotes at different times primary cancer of the lymph glands, *growths* from *embryonic vestiges, ditto* from melanotic epithelial cells, even acutely growing carcinoma—tends to hinder appreciation of this law In this phenomenon—the destruction of malignant protoplasm by the lymph glands—and its proper investigation in the laboratory lies our best hope of practical improvement in the treatment of "cancer" by ultra surgical means

The idea that "cancer" in ordinary circumstances is an inherited malady was long since disproved by the exhaustive examination of *numerous* cases which amply demonstrated the utter absence of heredity from the history of the majority, whereas—and this is the most practical and most cogent consideration—a *very* definite exciting cause is invariably found to have been in operation in the case of the relatively small minority who record "cancer in the family"

A few years ago *the late* Mr Alfred Haviland attributed to "towns situated on rivers which periodically overflow their banks" special proclivity to cancer Inquiry showed that the local practitioners *at those towns*—Shrewsbury, *for* example—had no knowledge of any remarkable prevalence of malignant diseases in the neighbourhood, that any apparent excess in mortality depended *on* the existence of a large hospital or infirmary attracting people from the adjoining counties Cancer shows no relation to any condition of *soil, climate*, or *food*, excepting *alcohol* The chronic congestion of mucous membranes induced by immoderate use of the latter has a conspicuous share in the generation of epithelioma, the most prevalent *form* of malignancy in the male sex

The discovery that mammary carcinoma secondarily infects the bone marrow in *ordinary* cases and that the cells lie dormant in that tissue for from two to six years before the disease again becomes manifest[6] has not only explained the mysterious course of that prevalent cancer variety but has also revealed with accuracy the conditions under which a radical cure is feasible by operation

I would respectfully urge that this association should make an attempt to place our knowledge of malignant disease *upon a truly scientific* basis. I submit *there might well be* founded an association cancer committee the function of which should be to differentiate and to classify the numerous varieties *known as "cancer"* Secondly, to place on record authoritatively the facts we already know respecting their genesis and [illegible] t with the numerou[illegible] trary, in my humbl[illegible] o their eventual success All are at present very seriously hampered by the confusion which prevails, by the vague terminology, by the absence of any clear understanding as to what facts or laws are established and what yet remain to be elucidated. The example of a well-known transatlantic laboratory after *several* years' work—*lately reported narrowly to have* escaped the withdrawal *of State* aid because it had effected *nothing*—will accentuate this suggestion, which I venture to think *would* constitute a more *practical measure towards* the diminution of cancer mortality than any hitherto inaugurated

TABLE OF DISEASES KNOWN AS "CANCER," WITH THEIR MODE OF CAUSATION

I —*Non-Congenital "Cancer"*

No	Disease	Tissue origin	Cause
1	Epithelioma	Epithelium of mucous membranes, epidermis	Continued mechanical friction aided by previous congestion
2	Carcinoma	Cells of acinar secreting *glands especially* those of the mamma	Any conditions hindering or pre*venting the natural* [illegible]
3	Sarcoma	The spindle shaped cells of the connective tissue	Always *of traumatic origin*, the injury being usually single and sudden
4	Cylindroma.	Cells of tubular *gland follicles* in the alimentary canal	Same as those of carcinoma, chiefly *worry and trouble*
5	*Lympho*-carcinoma.	Cells of lymph glands Also of the *other* lymphoid tissues *such* as the marrow and tonsils	Mechanical injury aided by previous congestive conditions May follow a violent muscular strain (See 24 cases Cancers and the Cancer Process p 337)
6	Rodent ulcer	Cells of short hair follicles, chiefly those in the outer root sheath	Same as of epithelioma.
7	Myo-sarcoma	Nuclei of non striated muscle. Hardly known except in connexion with the uterus	Usually a sequel of long standing *uterine myoma*. The "soft oedematous myoma" of Lawson Tait is the primary *form*.
8	Glioma (rare and obscure)	The neuroglia, nerve corpuscles (Virchow)	Most of the so-called "gliomata" appear to be due to embryonic *vestiges*. Others are true sarcomata consequent on traumatism
9	Endothelioma (rare and obscure)	Endothelial cell plates	Doubtful

II.—*"Cancer" of Congenital Origin complying with the Theory of Cohnheim*

No	Disease	Tissue origin	Cause
10	Blastoma (exceptional)	Embryonic residua. Elements usually multiple and complex (See Cancers and the Cancer Process, Appendix A)	Apparently of spontaneous *development* and so markedly *differing from ordinary* cancer

Varieties or species of the preceding—Scirrhus (chronic or mammary

---

[5] See causation table appended

[6] See cases detailed in Brit Med Jour, March 12th, 1892.

On mapping the peripheral region with the same 20 millimetre white object the outer limit does not reach out to the normal by 10 to 30 degrees, the loss being slightly greater in the temporal region than in the nasal; also, in searching the central region there is elicited a loss of power to detect white objects of one, two, five, 10, and even 20 millimetre size over a smaller or larger area according to the seriousness of the case.

The fields of these patients for red objects, taken with full illumination, show loss of central and of peripheral perception of the colour in varying degree, and the comparison of the red fields and the "dimly lighted" white fields shows that when there is a loss of perception of red there is always some loss of perception for white objects in the dim light both centrally and peripherally. The losses in perception of red and dimly lighted white objects are therefore coincident.

In following out cases over some months the variations in visual conditions according to the faithfulness with which the patient followed out the treatment indicated—abstinence from tobacco and the administration of strychnine—has been most interestingly shown. Four cases have been followed to the point of recovery; good visual acuity has been regained, contracted fields of vision for dimly lighted white objects have expanded to a close coincidence with those taken in full light, and scotomata for colours and dimly lighted white objects have been recovered from. On the other hand, lapses in the abstinence from tobacco and alcohol—and particularly as in one case where a drunken debauch intervened—were followed by loss both in visual acuity and extent of field in a marked degree.

It may be asked, what becomes of the statement made so often by patients suffering from the disorder that they see better at night than in the full daylight? a statement which, Fuchs[2] writes, was proved by him to be true in a few cases. The fields which I have taken give the answer to the difficulty. That the patients do not see more clearly on a change from full daylight to a dimly lighted room is certain, for the fields which I have taken in the dim light were contracted and showed scotomata which did not appear when taken in the full light. But several of the cases showed the characteristic signs of *fatigue* in a tendency to that helical curve which is so marked in hysterical amblyopia. Not infrequently an examination had to be interrupted and the patient allowed to rest, which rest the patient took by covering the eyes with the hand, before it could be satisfactorily concluded. It seems therefore possible that in a dim light of some duration there may be some partial relief from the fatigue produced by the constant stimulation of a bright light, so that a slight improvement in the visual acuity of the patient may result, and this irrespective of the freedom from the dazzling effect of bright light in their partially blind state.

There remains to be considered the bearing of the features shown by these fields on the views held as to the nature of tobacco amblyopia. The commonly accepted belief is that there is an axial and retro-bulbar neuritis, a limited affection of the papillary macular bundle seated in that portion of the nerve found within the optic foramen. In the discussion on retro-bulbar neuritis at the Manchester meeting of the British Medical Association in 1902[3] I ventured to express my doubts on this point in favour of the probability of the disorder being primarily one of the retina. These fields show that the amblyopia is not confined to the central region but that given a delicate enough test a loss of vision can be demonstrated for the periphery of the field and from the liability to symptoms of fatigue exhibited by these patients the defect may be conjectured to extend in some degree to the whole field of vision. In short, these subjective symptoms point very strongly to the correctness of Arlt's idea when he originally described the disorder as a *retinitis*—"retinitis nictaloptica."

An inquiry very naturally arises from these observations: Is the altered perception of an object in a diminution of the general illumination paralleled by a loss in the perception of objects whose luminosity is diminished whilst the general illumination remains unchanged? As I have shown, the peripheral field for a 20 millimetre white object in a healthy subject is the same whether taken in full daylight or in the dim light (one-tenth illumination), and I find that in *such subjects* the white fields in the full light are practically the same whether the object be 20 × 20, 10 × 10, or 5 × 5 millimetres; the reduction of the area of the white from 400 square millimetres to less than a tenth of this area does not diminish the perception of the white object. In the subjects of tobacco amblyopia this is not so; successive examinations of the peripheral field with 20, 10, or 5 millimetre objects show a smaller range of perception for the smaller objects as against the larger, the field for the smallest object being very similar to that for the 20 millimetre white object in the dim light.

CANCER FACTS AND CANCER FALLACIES:

A PLEA FOR THE MORE SCIENTIFIC STUDY AND TREATMENT OF MALIGNANT DISEASES.[1]

BY HERBERT SNOW, M D. LOND.,
SENIOR SURGEON TO THE CANCER HOSPITAL, BROMPTON.

UNDER this heading I would venture to call the attention of the section to the progressively increasing mortality from cancerous diseases in apparently all civilised communities; *and secondly, to point out more Socratico one or two of the* undeniable fallacies which seriously impede all present attempts at scientific investigation or practical amelioration. Of course, I can but touch the outermost fringe of this great subject.

In England and Wales the ratio of registered deaths from cancer to each million of persons living amounted in 1864 to 385; in 1874, to 461; in 1884, to 563; and in 1894, to 713. For the five years 1896–1900 it equalled 800·2 per 1,000,000. In 1901 "among males cancer was fatal at the crude rate of 691 per 1,000,000 at all ages and among females at the rate of 985 per 1,000,000."[2] In Ireland the cancer mortality in 1864 was 1498 in a population of 5,675,307. 20 years afterwards, with a decreased population of 4,962,693, is recorded an increased mortality of 1947. In 1902 the last published returns show 2861 deaths (females, 1575; males, 1286) to 4,432,274 inhabitants, or a ratio of 645 per 1,000,000. In Scotland the cancer deaths were 3503 (females, 2142; males, 1361) in June, 1900, out of a population numbering 4,436,958. This is at the rate of 800 per 1,000,000. In 1864, with 3,118,701 inhabitants, the cancer return was 1300; in 1884, with 4,962,693 people, it had increased to 2110. In New York State the 1,000,000 ratio was, in 1875, only 400; in 1885, 530; and in 1900, 670. In Connecticut it has risen from 520 in 1891 to 660 in 1900; in Massachusetts, from 610 to 710; in New Hampshire, from 560 to 710; and in Rhode Island, from 510 to 680.

Turning to European States, we find that in 1891 Austria recorded her ratio as 540; by 1900 it had increased to 700. In the same period Bavaria returns a rise from 890 to 990; Holland, from 790 to 930; Italy, from 430 to 520; Norway, from 610 to 920; and Prussia, from 450 to 610. Of the cities, Amsterdam returns for the same years, 1891–1900, a rise from 880 to 980; Boston, 690 to 810; Breslau, 860 to 1080; Brussels, 340 to 440; San Francisco, 600 to 1090; Stuttgart, 760 to 1270; Vienna, 1040 to 1210; and St. Petersburg, from 990 in 1891 to 1000 in 1899.[3]

Large as the above figures may seem there is considerable reason to believe that more accurate registration would augment them in no small measure.[4] Among ourselves a large number of deaths from cancer are certified as due to "gastritis," "enteritis," "intestinal obstruction," "stricture of pylorus," "dropsy," "internal tumour," and so forth.

Now the public—as voiced by the lay journals—credit us with complete ignorance of the causes of "cancer" and with utter impotence to eradicate it surgically or to ameliorate it medicinally. Is not the profession largely responsible for these absurdities? And could the influence of this great association be more beneficently utilised than in attempting to demolish them? What could be more fatally opposed to the interests of science than the common practice of grouping together a large number of diverse maladies under the single title "cancer"—no more definite and precise a term than "fever"? The point would be best appreciated by supposing someone to promulgate

further extension of the lesions Gradually all the sloughs were removed by fomenting and a large raw area was left *extending from just below the right ear down to the right* breast As the area was so large skin grafting was resorted to but the grafts refused to hold and a subsequent trial gave no better results Boric acid ointment was then applied for a time while later red lotion on lint gave excellent results Convalescence was slow and protracted the part granulating very slowly indeed Her general condition became much better in hospital iron having been persevered in steadily and except for a slight rheumatic attack she improved daily Her temperature throughout was slightly above normal usually about 99° F Twice however abnormal temperatures were registered once 110° and again 105° but on both occasions when the nurse again took the temperature it was found to be normal The cicatrix several times broke down when nearly completely healed but eventually after nearly five months in hospital she was discharged with the *part quite healed* but with an exceedingly large disfiguring cicatrix or rather cicatrices on her neck and breast

A CASE OF BULLET WOUND OF THE BRAIN

IN WHICH THE BULLET LODGED ABOUT 12 CENTIMETRES FROM THE POINT OF ENTRANCE AND WAS EXTRACTED FROM A DEPTH OF 6 5 CENTIMETRES FROM THE SURFACE OF THE HEAD [1]

BY WILLIAM SHEEN M S LOND, F R C S ENG

SURGEON CARDIFF INFIRMARY CONSULTING SURGEON SEAMEN'S HOSPITAL CARDIFF SURGEON IMPERIAL YEOMANRY FIELD HOSPITAL SOUTH AFRICA 1900

With a Note on the X ray Methods in the Case by WILLIAM MARTIN *M A M B C M Glasg, Assistant Surgeon to and Medical Officer in charge of the Electrical Department Cardiff Infirmary*

A MAN aged 23 years a stoker was struck on the forehead by a revolver bullet while standing on the cab of his engine The bullet was fired from a garden near the railway line at a distance of from 25 to 30 yards The man fell but loss of consciousness was only momentary The wound was enlarged and probed without result He walked to a train and was taken a distance of about 20 miles to the Cardiff Infirmary and was admitted there at 6 30 P M on Nov 28th 1903 three and a half hours after the accident

Detailed examination immediately after admission showed an entire absence of symptoms There was no evidence of the position of the bullet Three hours later vomiting occurred In the morning he was semi conscious grunting moved his limbs when told to and said yes and no The reflexes were unaffected The pupils were equal and were of medium size and reacted Slight paralysis of the lower side of the face was present on the right side The temperature was 99 8° F and the pulse was slow and full The head was shaved A skiagraphic view showed indistinctly the position of the bullet Antero posterior and lateral x ray photographs were taken and these being developed the man was anæsthetised on Nov 29th at 3 P M In the intervening period his temperature had gradually risen and was now 102° The entrance wound was situated 2 5 centimetres *to the left of the middle line and 2 5 centimetres* above the orbital arch it had contused edges and had been enlarged by a crucial incision The bone and dura mater had been lacerated and brain substance oozed from the wound There were no fissures radiating from the wound in the bone A suitable toilet was made of the wound and it

The

to its

1

The subsequent progress was one of slow general improvement complicated by the incidence of paresis of the right arm and right side of the face with motor aphasia symptoms all of which gradually subsided The temperature reached normal on the fourth day after operation and *remained there Examination of the optic discs by Mr* F P S Cresswell on Dec 1st showed them to be healthy *and a blood count by Dr Cyril Lewis on Dec 2nd* gave 10 400 leucocytes per cubic millimetre There was loss of control of the excreta until Dec 3rd The paralysis of the face was limited to the lower part the associated movements being good Weakness of the right arm was noticeable on Dec 1st and aphasia on the 2nd The paretic symptoms became more marked during the next four days when slow improvement commenced T

mometer grip *nil* inabil

to move the elbow and

arm No sensory disturbances were noted at this time but later there was numbness in the little and ring fingers which after the second operation extended to the middle and index fingers The aphasic symptoms were of the ordinary motor type Whilst unable to speak to repeat or to name objects comprehension was perfect and he was always able to indicate the number of syllables in a word No disturbances of the special senses were present The stereognostic sense was good After passing through a state of mental confusion characterised by laughing and silliness he completely regained consciousness by Dec 7th The first *person he recognised was the man who shot him, he called* out this man's name and indicated a dislike to his presence On Dec 16th the dynamometer grip was right 40 left 60 and the facial paralysis was almost gone The aphasic symptoms disappeared more slowly but by the end of December only occasional hesitation or difficulty in getting out words remained together with confusion and stuttering when he embarked on a long sentence He remembered his accident and admission to the infirmary then there was a blank for three or four days when he remembered his mother sitting by his bedside

The only further points to be noted up to the date of the second operation were intermittent attacks of left parietal and frontal headache and on Dec 18th a bad attack of general headache with temporary increase in the aphasia and arm weakness this passed off On Jan 16th he got up and on the following day slight weakness of the right leg was noted together with a tendency to throw out the right foot when walking The right knee jerk was found slightly more marked than the left previous examinations had shown no difference

The second operation was performed on Feb 9th—i e, ten weeks after the injury The forehead wound was soundly healed Several skiagrams had been taken and a stereoscopic view was prepared showing the position of the bullet Chloroform was administered by Dr W G Williams Mr A Brownlee the resident medical officer assisted, and Mr Martin Dr I W Parry of Ferndale (who first saw the patient) and other gentlemen were present A flap was turned down behind the left ear and a one inch disc of bone was removed above and behind the meatus This bone opening was enlarged downwards and forwards, the dura mater was opened and search was commenced for the bullet by entering a probe 3 5 centimetres above the meatus and 2 5 centimetres behind the inter meatal line *and passing it in in the horizontal plane of the head* for a depth of 6 7 centimetres The bullet not being felt Hedley's telephone probe was passed in the same line and after feeling a moment a rather doubtful tap was heard The probe was withdrawn and a pair of ordinary dressing forceps was passed in and felt the bullet which bobbed about in an elusive way at the end of the forceps suggesting the possibility of its being in a cavity A first attempt to grasp and to remove it proved unsuccessful but on reintroducing the forceps it was seized and removed with a little adherent brain substance The length of forceps introduced measured 6 5 centimetres from the general skull surface *As there was considerable increase of intracranial* tension some of the brain substance had to be removed before the dura mater could be brought together The disc of bone was replaced and the wound was closed with drainage

The after progress was uneventful There was no paralysis or aphasia The tube was removed on the day following the operation and the stitches were removed on the eighth day when the wound was found to be healed completely Exactly three weeks from the operation the man got up There was still slight weakness of the right arm and leg The dynamometer grip was right 60, left 90 Dimness of vision was complained of particularly in the right eye On Feb 22nd Mr Cresswell reported: "? slight contraction of the field of vision outer side of right eye; in both eyes the optic discs are somewhat pale in the temporal half and arteries small; otherwise the fundi are normal and the media clear. Vision: R. E. $\frac{6}{24}$, J. 8; L. E. $\frac{6}{18}$, two letters, J. 8." On March 24th a further report stated: "Patient has mixed astigmatism. Vision: R. and L. E. $\frac{6}{12}$, J. 16. Corrected by glasses, $\frac{6}{6}$, J. 1. Pupils equal, semi-dilated. Right does not react so well to light as left. Fundi normal. Visual field: L. E., normal; R. E., ? some slight contraction in lower and outer part of field." The patient was supplied with suitable glasses. One other interesting point should be mentioned. When the hair commenced to grow after shaving it failed to grow in the right temporal region. The hair was slowly growing over this part when the patient left the hospital. He was discharged on March 25th, 1904, having been kept in for so long a time so as to be under observation.

---

[1] A paper read before the Cardiff Division of the South Wales and Monmouth Branch of the British Medical Association

Such cases as the above are necessarily rare in civil practice, but they are also rare in military, particularly modern military, practice. My own South African experience,[2] coupled with such examination of the literature of the South African and other recent wars as I have been able to make, has not furnished a parallel case—i.e., I have not been able to find a case where the bullet has been removed from the depths of the brain entirely on the results of x-ray localisation. Mr. W. H. A. Jacobson's observations[3] are the most instructive and complete that I have been able to find; he gives details of one case (Braatz) where x-ray localising methods resulted in the successful removal of the bullet, but the depth of the bullet is not stated.

The various interesting points of the case are best considered *seriatim*, but before doing so I wish to express my great indebtedness to Mr. Martin (whose report follows) for his careful and accurate localising work which helped to bring the operation for extraction to a successful issue.

Why did not death immediately ensue?—In studying bullet wounds of the brain one is struck with the uniform fatality of the cases when the bullet has passed right through the head or when it has lodged deeply. Injuries of the fronto-parietal type, as Makins has pointed out,[4] are particularly fatal. This fatality is due to the high velocity of the modern small-arms bullet which, as it rushes into the brain, scatters waves of destruction in all directions; whereas a spent bullet or a bullet of initial low velocity simply pushes its way into the brain substance and the damage it does is largely limited to its track. An indication of the damage done to the cranium by a high-velocity bullet is seen in the fissures which radiate in the bone around the wound of entrance; such fissures were not present in my case. Similar destructive waves would be produced in the brain tissue beneath. The size and structure of the bullet are other factors in determining the amount of damage which need not be further dwelt on. The exact course taken by the bullet—in my case above the ventricles and basal ganglia—also, of course, helps to determine a favourable result or the reverse.

The initial delay of symptoms.—The gradual onset of symptoms some hours after injury must be attributed to a localised "œdema of the brain." There was no concussion—so common in injuries by high-velocity bullets—and the symptoms were not sufficiently immediate for hæmorrhage and not sufficiently delayed for inflammatory processes.

The leucocyte count.—This, together with the absence of optic neuritis, was valuable in negativing meningitis or commencing abscess, particularly in the presence of a raised temperature.

The bullet track.—A study of these cases shows that surgeons recognise a "bullet track" along which probes can be passed. In my case there was no bullet track. The brain tissue seemed to have closed up behind the bullet. Similarly in using instruments in the second operation it was noticed that one instrument did not leave a track for the next. Hence, the necessity for avoiding reintroduction of instruments (*vide infra*).

Probable course of the bullet and point of lodgment.—Knowing the localising points careful observations on a skull and brain of about the same size as the patient's enabled me approximately to determine these. At one time it appeared possible that the bullet had been arrested in its course by the tentorium cerebelli—a not unlikely thing to happen to a bullet travelling with low velocity—and had become imbedded in that membrane. This condition, which would have increased the difficulty of extraction, was negatived by later photographic methods. Entering, then, 2·5 centimetres above the left orbital arch and the same distance to the left of the middle line, the bullet passed backwards, downwards, and slightly inwards (the man probably had his head bent forwards when struck) for a distance of 12 centimetres, lodging at a depth of 6·5–7 centimetres in relation to a point 3·5 centimetres above the external auditory meatus and 2·5 centimetres behind the inter-meatal line—i.e., lodging about 1·5 centimetres from the middle line and 2·5 centimetres above the tentorium. The bullet traversed the left frontal lobe and the innermost fibres of the corona radiata, passing gradually backwards and inwards into the callosal convolution, in the hinder part of which it lodged, the corpus callosum being therefore probably uninjured.

Comparison of symptoms.—It is difficult to compare the symptoms exactly with the anatomical data as one does not know to what extent they were due to the primary passage of the bullet and to what to the secondary disturbances around the bullet path. There was interference with the functions of Broca's area, probably due mainly to subcortical damage, as there was not the slightest impairment of the understanding of words and the man could always correctly indicate the number of syllables in a word. The motor areas for the face and arm were interfered with less and that for the leg hardly at all. There was hardly any disturbance of sensation, indicating the little that the callosal convolution had to do with that function.

Eye symptoms.—The disturbance of vision after the second operation was somewhat more than could be accounted for by the astigmatism present and, as will be seen by a comparison of Mr. Cresswell's two reports, there was some improvement in the course of a month. It is quite possible that at the second operation there was some temporary injury to the connexions of the left half vision centre.

Localised baldness.—This occurred on the side opposite to the injury. Was it due to some trophic disturbance in the skin or to the action of the x rays, this being the side that was exposed to the rays? The exposures made were short, on no occasion exceeding two minutes, and there were never more than two photographs taken on one occasion. Fluorescent screen observations were only made once for a short time and that was on the day of admission.

Was the operation for extraction of the bullet justifiable?—The man was nearly free from symptoms and apparently on the road to complete recovery. There were, however, certain symptoms—viz., intermittent headache, pain on moving the head, and at least one definite, severe attack of headache with temporary remission of symptoms. Then one realises that the heavy bullet may change its position; it being felt as if in a cavity at the second operation supports this possibility. Cases where the foreign body is left often do not do well; in addition to headache there may supervene mental disturbances, fits, cerebral abscess or softening, various paretic symptoms, &c. The disturbing influence on the patient of the fact that a foreign body is in his brain has also to be taken into account; in this case the man was a factor in determining operation, for he was very desirous to have the bullet removed. Finally, in approving the justifiability of removal one might point out that an operation conducted aseptically and carefully, even if the bullet were not discovered, would not be likely to do any harm, and if there were, an increase of intracranial tension, as in this case, would do good quite apart from the bullet extraction.

Value of the x rays.—The chief point in the case is the illustration of the value of localisation by the x rays. It would have been impossible to localise the bullet to any serviceable degree without such aid. Unfortunately, however, one cannot say that the extraction of a bullet is always assured after accurate localisation. The probability lessens the greater the depth of the bullet from the surface, for the deeper the probe or other instrument has to go the more likely is its point to deviate from the exact path.

Instruments required in these cases.—The telephone probe I used was wrongly constructed so must be dismissed as a factor in this case. Practically the extracting forceps found the bullet. The telephone probe, however, is of undoubted utility but in order to obviate as far as possible the reintroduction of instruments a "bullet-probe forceps" is desirable, an instrument which can be attached to the telephone receiver and which both detects and extracts the bullet. Further, such an instrument should be graduated so that it can be at once noted when it has entered the required depth. On these lines I am having certain forceps constructed with suitable telephonic attachments and I purpose to publish a detailed account of them at a later date.

[2] [illegible] ital Reports, vol. iii. Surgical Report of the [illegible] Company, by Charles Stonham. London: A. L. [illegible]

[3] Jacobson and Steward: The Operations of Surgery, vol. i., fourth edition, 1902, p. 260; "Operative Interference in the Case of Foreign Bodies in the Brain."

[4] Makins: Surgical Experiences in South Africa.

The patient returned to work on July 4th last, and has, so far as I know, continued at work. He discarded his glasses, saying that he could see better without them, and is in all respects well.

Note by MR. MARTIN.—In all cases before the removal of foreign bodies is attempted accurate localisation is advisable but when the foreign body is inside the cranium such localisation is absolutely necessary. In such cases as the above, without the aid of the x rays surgery is helpless. In Mr. Sheen's case the ordinary routine was gone through. Shortly after admission a screen examination was made to get some idea of the locality of the foreign body and skiagrams were taken. When the question of removing the bullet was brought forward skiagrams were taken laterally and antero-posteriorly and localisation was performed by the double impression on the single plate and the Mackenzie Davidson cross-thread localiser. By this means it was found that the depth of the bullet from the plate was 6·9 centimetres. About five centimetres were allowed for scalp, &c., intervening between the plate and the external surface so that it was calculated that the centre of the bullet, approached on the horizontal plane of the head from a point 3·5 centimetres above the left meatus and 2·5 centimetres behind the intermeatal line, would be found at a depth of 6·4 centimetres. This distance was checked by the antero-posterior view which gave the centre of the bullet between 6·4 and 6·5 centimetres in a line from outside the bony cranium.

The night before the operation for removal of the bullet, in order to make certain that no serious alteration in its position had taken place since the localisation, stereoscopic impressions were made and from the wet plates prints being obtained by artificial light the surgeon was enabled to see the bullet *in situ* before beginning the operation. A stereoscopic view is of great help, giving in the matter of relations and direction confirmation of other methods of localisation. Stereoscopic views of foreign bodies lying deep in the cranial cavity do not, however, give a very clear idea of the exact depth owing to the absence of intervening landmarks *in the same way that distances at sea are so difficult to* estimate. The uniformity of the surfaces of the parietal [illegible] was [illegible] superimposed upon the other in crimson, to be viewed through green and crimson glasses This, I understand (February, 1904), is the first time that this method has been applied to x-ray work and I venture to suggest that there may be a future for the method as a means of illustrating stereoscopically x-ray photographs in medical journals.

Cardiff.

CONGENITAL WORD-BLINDNESS.[1]

BY SYDNEY STEPHENSON, M.B., C.M., F.R.C.S. EDIN.,
OPHTHALMIC SURGEON TO THE EVELINA HOSPITAL, ETC.

THAT some children are much slower than others in learning to read must be an observation as old as the art of reading itself. It is, however, only within the last few years that such tardiness in otherwise bright children has been recognised by a special name and studied with some approach to scientific accuracy. The first writer to describe the condition was Dr. W. Pringle Morgan.[2] His patient was a lad, 14 years old, who, although intelligent in every other way, experienced the utmost difficulty in learning how to read. The defect was so marked that despite seven years' constant application he was able to spell out only monosyllabic words. Figures, curiously enough, he could read fluently and simple arithmetical sums were done fairly well. A couple of years after the publication of Dr. Morgan's modest communication Dr. H. C. Bastian[3] described a similar case in a young man, aged 18 years. This patient was so extremely slow in learning to read that his tutor almost despaired of ever being able to teach him. Dr. James Hinshelwood[4] of Glasgow next took up the subject, analysed the cases previously reported, and added two new examples to the growing list. To Dr. Hinshelwood undoubtedly belongs the credit of having been the first to describe the condition scientifically, to assign it to a defect in the vis [illegible] and letters, and to name it " [illegible] It is highly probable that but [illegible] the two previous communications would have failed to attract the attention they have since received. Mr. Nettleship[5] next described five cases and in doing so spoke of having been familiar with the condition for many years, thinking and speaking of it as a congenital want of power to acquire knowledge by printed signs. In the year 1902 Dr. Hinshelwood[6] reported two further cases and took the opportunity of elaborating several of his previous arguments with regard to the essential nature and characteristic symptoms of the condition. The other reported cases up to the date of writing include one by Lechner[7] and two by Wernicke.[8]

So far, then, 14 cases of congenital word-blindness have been reported by six authors. To conclude, nevertheless, that this congenital defect is rare on account of the small number of cases reported in literature would be to commit a logical fallacy. Almost everybody who has written on the subject, notably Dr. Hinshelwood, has commented upon the fact that cases are not so rare as the scarcity of records might lead one to infer. Slight cases are almost certain to be overlooked in the hospital out-patient room where surgeons are busily occupied and parents seldom capable of giving a clear account of their children's ailments. On the other hand, congenital word-blindness, especially when of slight degree, is much more likely to be recognised in the consulting-room and as a matter of fact most of the cases appear to have been met with in that way. At the same time, there is no present ground for the belief that the condition is commoner in children of the poorer classes. One point should be mentioned—namely, that 85 per cent. of the cases have been reported by ophthalmic surgeons, an observation that goes to show that patients, in the first instance at any rate, usually seek special rather than general medical advice.

The subject of word-blindness is interesting both from the medical and from the educational standpoint, a fact that leads me to place on record two instances—one slight and the other severe—that have fallen under my notice. The facts are as follows.

CASE 1.—The patient, a boy, aged nine years, was seen on Dec. 10th, 1898. Although a painstaking boy he had experienced unusual difficulty in learning to spell and to read. Arithmetic also caused him difficulty. He complained that his eyes got sore after doing his lessons. He had considerable powers of observation and of insight. For example, he could carry in his mind the details of a machine or of a building and could reproduce them on paper. He reasoned well. In disposition he was considerate and sympathetic. His father, an exceptionally cultured man, believed that his son's failure to read was due not to a mental but to a developmental defect. The boy was *of a nervous temperament* but was tolerably well-grown for his age and apparently in good health. His relative visual acuity was almost normal (V. = $\frac{6}{6 \text{iii.}}$ and No. 1 Jaeger), but he deciphered the letters on the Snellen distant type in a curiously hesitating way, a difficulty that extended both to the large and small letters. The small types of Jaeger were read slowly and with many mistakes, but what struck me as peculiar was that the larger type on the same test was read with just as must difficulty. Under a cycloplegic: R. V. = $\frac{6}{12} + 1{\cdot}50 = \frac{6}{6}$; L. V. = $\frac{6}{12}$ ii. $+ 1{\cdot}50 = \frac{6}{6}$. The fundi were normal; the fields of vision for white were full; the colour sense was not noted. Spectacles (+1·0 *D.* spherical) were prescribed for reading and the father was advised to educate the lad privately. When I saw the patient again, some six months later, I found that he had made considerable progress with his reading. The boy died from influenzal peritonitis on Jan. 15th, 1904, that is to say, some five years after he first came under my notice. According to information kindly furnished by his father distinct progress had been made in the last year of life. His spelling had improved, especially of Latin words, a language that is more phonetic than English. The improvement had extended to reading and to arithmetic. He was learning to draw from the solid and was doing it well. "I am exceedingly glad," the father wrote, "that, following your advice, I did not send him to school. Now that the little fellow is gone it would have been a life-long regret to me if I had embittered his last year of life by placing him where he could not have learned without pain."

[1] [illegible] the Study of [illegible]

[3] [illegible] London, 1898.

[8] Wernic[illegible] [illegible]ptember, 1903.

CASE 2.—The patient, a boy, aged ten years, was seen by me on Jan. 15th, 1903. This excitable lad had been affected for about five years with spasmodic movements of the face, eyelids, mouth, and neck, especially marked when under the influence of emotion, with a so-called "habit spasm," in fact. He was brought because he had experienced great difficulty in learning to read and was believed on that account to be "short-sighted." He had never suffered from scarlet fever, rheumatism, or "growing pains." His heart sounds were normal and he was not subject to sore throats, such as many rheumatic children are affected with. He is deaf (= watch close to ear) on the right side, owing to long-standing otorrhœa. The family history was as follows. His great-grandmother died at the age of 75 years from a third stroke and she was paralysed down one side for many years before her death. His mother, maternal grandmother, and younger sister had all been affected with rheumatism, the last-named after an attack of scarlet fever. His eldest sister, now 13 years of age, read well when she was eight years old. His father and mother both come from large families, but no reading defect amongst the members had ever been heard of. There were no insanity or hysteria or "fits" and no miscarriages or stillbirths. Upon examining the lad sight was found to be R. $= \frac{6}{36}$; L. $= \frac{6}{24}$. Atropine was prescribed and a few days later refraction was estimated with the following results: R.V. $= \frac{6}{36} \; \frac{+1 \cdot 50}{+3 \cdot 5090^\circ} = \frac{6}{12}$; L.V. $= \frac{6}{36} + 4 \cdot 090^\circ = \frac{6}{12}$. The fundi were normal. Glasses were prescribed for constant wear. About a year later (Jan. 13th, 1904) I obtained a much more complete account of the patient's tastes, peculiarities, and defects. He was described as being "as bright as a lark and as sharp as a needle." He pondered over books but did not enjoy them owing to the difficulty of reading them. Handwriting was read as badly as printed matter and figures were read as imperfectly as either. Dictation was badly done. Although unable to express himself in writing yet he could copy sentences from a printed book correctly. He was almost unable to learn by heart from a printed page but he could memorise quickly and retain tenaciously anything told or read to him. Thus, he learned by rote 14 verses, each containing four lines, in two days and repeated them to me without hesitation or mistake. His memory was excellent. At such games as cricket, football, draughts, and dominoes he could play well. The lad, before he came under my notice, was educated at a boarding-school at the seaside and an inspection of his term reports brought to light certain interesting points. From the earlier reports it seemed evident that his teachers had no idea of the lad's peculiarity, for they characterised him as "inclined to be idle" (Christmas, 1901). In summer, 1902, we find that "he has made especial progress in arithmetic," although it is to be noted that he obtained only 20 per cent. of the total available marks in that subject. A similar comment with regard to arithmetic is made in the report for the term ended Dec. 17th, 1903. In short, the boy's strong subjects were divinity, history, and geography, in all of which he learned the work presumably by the exercise of a very active auditory memory.

It cannot be doubted, then, that there exists a congenital condition not necessarily associated with any other defect (mental or physical) where the learning of letters or of words from printed or written characters is difficult or, it may be, even impossible. This congenital letter- or word-blindness may be due, as Dr. Hinshelwood and Dr. Lechner surmise, to a congenital defect in the visual memory centre for words and letters. The fact is probably not without significance that of the total number of cases 13—that is, 82·25 per cent.—have been met with in males. The ages of the patients (given in 15 instances) ranged from seven to 23 years and averaged 13 years. In other words, they usually fell under notice at an age when the nature of their peculiarity would be forced upon the attention of parents and teachers. A neuropathic family history was forthcoming once only—viz., in one of Wernicke's cases—where the father, an intemperate man, died insane and the patient's elder brother was weak-minded. It may be noted in passing that another brother could play several games of chess simultaneously and also without seeing the chess-board. The two brothers of one of Mr. Nettleship's patients were stammerers. Some of the sufferers from alexia have evidently been of a nervous temperament, as witness one of Wernicke's patients, a female, 19 years of age, said to be hysterical; Lechner's case, a boy, 13 years of age, said to be "very nervous"; and in the two cases described in the present communication. The previous illnesses of the patients offer nothing calling for particular remark. As a rule they enjoyed good health.

Vision was recorded in ten of the cases and was normal in all except two. Refraction, specifically mentioned ten times, was emmetropic once and hypermetropic with or without astigmatism in the remaining nine cases. The fundus oculi was examined in six patients with negative results. The fields of vision and the colour sense were normal in the two cases in which they were investigated.

General intelligence was good in 13 of the 16 cases and may well have been so in the other three cases, but no definite note was made with regard to the point. The ability to read figures existed in seven of the cases, was not noted in seven cases, and was poor in my own cases. In this connexion I may just say that several years ago I saw a lad, aged ten years, who experienced extraordinary difficulty in reading figures without any corresponding difficulty in regard to letters and words. There was a trifling amount of hypermetropia (0·75 D.) but his eyes were otherwise normal. Unfortunately, I saw the patient once only and have failed to trace him since. As to music, mentioned twice only in the series, it was stated that patients experienced no trouble in that respect. The auditory memory appears to have been developed highly in most of the patients. Thus, one of Wernicke's patients could speak two languages correctly; one of Hinshelwood's patients concealed his difficulty in reading for a time by learning his primer off by heart; Lechner's patient is stated to have known the contents of his school books by rote; and my second patient could memorise well and quickly anything told or read to him.

What improvement can be expected in these cases? It will naturally vary according to the original severity of the case and the educational means adopted. It may be considerable. It may, furthermore, take place comparatively quickly, as shown by one of Hinshelwood's cases, where a boy who had not been able to read after upwards of four years at school made very considerable progress in recognising letters by dint of constant practice during seven weeks. The improvement in these cases is usually described as "slow but satisfactory." Perhaps the most striking case is one mentioned by Nettleship, where a boy who suffered from a marked degree of alexia eventually learned to read easily and 19 years after he was first examined had become a lawyer. It may be concluded therefore that with special training even severe cases of congenital word-blindness are capable of considerable improvement. It is clear, moreover, that the earlier such training is begun the better are the results likely to be. Hence the importance of recognising the defect at as early an age as possible.

The diagnosis offers few difficulties if once the fact be firmly grasped that there is such a thing as congenital inability to read. At least, difficulty would be likely to arise only when the word-blindness co-existed, as in my second case, with a considerable error of refraction. Even in those circumstances the history should guard one against error, while the fact that the patient experienced exactly the same difficulty in reading large as he did small print would strongly suggest the presence of this curious congenital defect. It is interesting to add that more than one of the case-histories comment upon the fact that the patient never read for pleasure. In view of the particular attention now being paid to degeneracy amongst our poorer school children it is pretty safe to predict that congenital alexia will be found to be commoner than hitherto suspected, even by the medical profession.

Welbeck-street, W.

EPITHELIOMA OF THE TONGUE IN WOMEN,

WITH NOTES OF TEN CASES.

By CHARLES R. KEYSER, F.R.C.S. ENG.,
SURGICAL REGISTRAR TO THE CANCER HOSPITAL; LATE SURGICAL REGISTRAR TO ST. GEORGE'S HOSPITAL.

COMPARATIVELY recently Mr. R. Clement Lucas[1] stated that in all his professional experience he had only once removed a tongue from a woman for epithelioma. As I have lately come across a few instances of this disease I have looked up the records of St. George's Hospital and the Cancer Hospital and have been able to find ten hitherto unpublished cases. There can be no doubt that epithelioma of the tongue in women is decidedly uncommon, but the frequency with which it occurs varies apparently according to the sources from which the cases are derived. Thus Butlin and Spencer[2] state that the disease is found in women in 15 per cent. of all cases of epithelioma of the tongue. This agrees almost exactly with the figures given by A. E. Barker,[3] who found that out of 293 cases of cancer of the tongue, collected from seven different clinics, both at home and abroad, there were 46 females, or 15·6 per cent. The same author, however, mentions that Berg noted 11 instances out of 21 cases at the Serafimer Hospital, Stockholm. On the other hand, from the Hospital Reports of four London hospitals I have collected 593 cases; of these 48 were in women. This works out at 1 in 12·3, or almost exactly 8·09 per cent. During the last 12 years at St. George's Hospital there have been 32 cases of epithelioma of the tongue subjected to operation; six of these were women or 18·8 per cent. Stanley Boyd and W. H. Unwin[4] collected 34 cases from private and hospital practice from 1891 to 1902 both inclusive; only three of these were in women. A. D. Fripp and R. H. J. Swan[5] found that epithelioma of the tongue was seven times more common in men than in women, whereas sarcoma was only twice as common and usually appeared between the ages of 15 and 30 years. Butlin and Spencer[6] also give the following list as showing how the percentage frequently varies according to different authorities: Jessett, 400 cases, 15 per cent.; Whitehead, 104 cases, 15 per cent.; Gurlt, 14·6 per cent.; Lardau, 16 per cent.; Czerny, 26 cases between 1878 and 1888, all males; Kocher, 69 cases, three women; Krönlein, 40 cases, two women; Wölfler, 3·4 per cent.; Weber, 12·2 per cent.; Sigels, 29·5 per cent.; Clarke, 28 per cent.; Paget, 36 per cent.; Bruns, 33 per cent.; and Hayn, 43 per cent.

Age.—This does not seem to differ to any appreciable extent in the two sexes. In men the disease is uncommon before 40 years and occurs with great frequency between the ages of 50 and 60 years. In 21 cases of cancer of the tongue in women which I have collected from various sources the average age was 54·7 years. J. Hutchinson, jun.,[7] however, refers to a case where a girl, aged 19 years, was afflicted with the disease; the growth was removed and recurred. It was again removed and two years later she was free from recurrence. Butlin saw a case of a woman, aged 24 years; Spencer one at the age of 22 years; and Harrison, quoted by the two former authors, saw one in a girl, aged 20 years, who died in less than six months.

Causation.—As in men, the new growth is almost invariably preceded by prolonged local irritation the result of either rough, carious teeth, a badly-fitting or broken tooth-plate, or syphilis of the tongue. The so-called pre-cancerous condition or leukoplakia is commonly [illegible] tongue, as has been stated by some authors. Excessive smoking has also been adduced as a common predisposing cause, but this, again, does not appear to be at all common. Thus Barker[8] states that in Finisterre, where all the women smoke short pipes, Hertaux collected 100 cases of cancer of the lip and tongue; not a single case occurred in women. In Wales, also, where the women commonly smoke short clay pipes, the disease is not often observed. In only one case out of those which I have collected was there a history of smoking mentioned. In this connexion it is interesting to note the following facts issued in a special cancer supplement by the Registrar-General of Ireland for the year 1901. The total number of deaths from cancer in England, Scotland, and Wales has been steadily increasing from the year 1864 up to 1900. The figures now reach 8·3 for England and Wales and *8·0 for Scotland per 10,000 living inhabitants. In Ireland,* although the same steady increase is seen, the death-rate has always been about 2 degrees lower and is now 6·1 per 10,000. The death-rate from cancer of the tongue in England and Wales for the years 1897 to 1901 inclusive is 11·6 per cent. Excluding the year 1901, which includes *all* forms of malignant disease of the tongue, the death-rate is 11·3 per cent. However, in Ireland, although the total number of cases of cancer is less than in England, yet the death-rate from cancer of the tongue for the years 1898 to 1901 inclusive is 13·3 per cent. or 2 per cent. higher. Whether this is due to the fact that many women in Ireland smoke I should not like to say, as there are many other factors which may be concerned. In neither the appearance, situation, course, diagnosis, prognosis, nor treatment does the disease in women appear to differ from that in men. The Museum of the Royal College of Surgeons of England contains three specimens of cancer of the tongue occurring in women (Nos. 2271A, 2273F, and 2273L), but neither the specimens nor their histories show any extraordinary features. The notes of my cases are as follows.

CASE 1.—The patient was admitted into the Cancer Hospital in August, 1886, for epithelioma involving the left half of the tongue; it was freely removed. The patient was last seen on April 6th, 1904, and was in very good health and showed no sign of recurrence.

CASE 2.—A woman, aged 68 years, was admitted into St. George's Hospital on April 6th, 1892, under the care of Sir (then Mr.) William H. Bennett. The history was that the tongue had been sore and painful for six months. There was no history of syphilis. The patient was losing flesh. There was a hard mass slightly raised above the surface on the left edge and tip of the tongue; some ulceration was present. The floor of the mouth was not involved; no glands were felt. The anterior half of the tongue was removed with scissors the next day; recovery was uneventful and the patient was discharged on April 23rd.

CASE 3.—A woman, aged 60 years, was admitted to St. George's Hospital on May 10th, 1893, under the care of Mr. T. P. Pick. For five weeks she had had pain in the left side of the jaw and side of the head and had noticed a little white spot on the tongue on the left side. There was a deep ulcer with raised and intensely hard edges on the left side of the tongue and the floor of the mouth was implicated. On May 20th the left half of the tongue was removed by Whitehead's method and on July 3rd the whole of the growth in the floor of the mouth was excised. The patient was discharged on July 12th.

CASE 4.—A woman, aged 23 years, was admitted into St. George's Hospital on Jan. 5th, 1894, under the care of Mr. J. W. Haward. Six weeks previously she noticed slight soreness and a lump on the right margin of the tongue. She had been wearing a tooth plate in the upper jaw for two years. There was no sign or history of syphilis. On examination there was an ulcer far back on the right side of the tongue with raised and irregular surface, whitish in colour, and very hard. No enlarged glands were felt. On Jan. 19th a nodule of the size of a split pea was noticed on the dorsum of the tongue near the ulcer. On the 27th the tongue was split down the middle line and the right half was removed by means of an écraseur. The growth was examined microscopically by Dr. H. D. Rolleston and was found to be a squamous-celled epithelioma. The growth recurred in the tonsil and glands of the neck and the patient died on Dec. 4th.

CASE 5.—A woman, aged 48 years, was admitted into St. George's Hospital on Jan. 18th, 1898, under the care of Mr. Pick. For eight months an ulcer on the left side of the tongue had been noticed (? due to a decayed tooth). The ulcer was not increasing in size and the patient was not losing flesh. On the left side of the tongue a large excavated ulcer with everted edges was seen; there was induration around and the ulcer was irregular in shape. The tongue was freely moveable and there was no pain. A jagged, carious tooth was found exactly opposite the deepest part of the ulcer. No enlarged glands were felt. On Feb. 3rd a small portion was removed and examined microscopically by Dr. Rolleston who pronounced it to be a squamous-celled epithelioma. On the 10th the left half of the tongue was removed by Whitehead's method. The patient made an uneventful recovery and was discharged on the 28th.

[8] Loc. cit.

CASE 6.—A woman, aged 69 years, was admitted into St. George's Hospital on July 4th, 1900, under the care of Mr. Haward. For six months she had had much pain and had noticed a sore on the left side of the tongue which was rapidly increasing in size. She had had syphilis 25 years ago. A large ulcer with raised edges and an indurated base was found occupying the whole of the left side of the tongue from the tip to the anterior pillar of the fauces. It also extended beyond the middle line and involved the floor of the mouth, so that the patient was absolutely unable to protrude the tongue. She was losing weight and an enlarged gland was felt in the submaxillary region. On July 16th the growth was removed by means of an écraseur. Histologically the growth was a squamous-celled epithelioma but in addition showed evidences of syphilis. The patient died on the 27th.

CASE 7.—A woman, aged 72 years, was admitted into the Cancer Hospital on April 1st, 1903, under the care of Mr. F. B. Jessett. One year ago she noticed a small round ulcer on the dorsum of the tongue which caused pain in the ear. The ulcer gradually increased in size and "caused the saliva to dribble away." One sister died from cancer of the stomach. On examination the whole tongue was occupied by a cancerous growth which extended to the floor of the mouth. The tongue was quite fixed and there was an enlarged gland to be felt in the right submaxillary region. On the left side a gland of the size of a pea and freely moveable was present over a portion of the growth which extended down the left side of the larynx as far as the level of the cricoid cartilage. The patient died on July 7th.

CASE 8.—A woman, aged 52 years, was admitted into St. George's Hospital in February, 1903, under the care of Mr. A. M. Sheild. A sore place was first noticed on the left margin of the tongue in April, 1902. In July this became hard and a growth of the size of a pea became evident. No pain was suffered and the general health was good. At the posterior part of the left margin of the tongue there was a small rounded ulcer about one-third of an inch in diameter, with slightly thickened edges. The base was clean but somewhat indurated. The rest of the tongue was quite healthy and no enlarged glands were felt. On March 2nd an incision was made in the left submaxillary region and the submaxillary gland was removed; the tongue was then pulled down and the ulcer and the portion of the tongue around were excised. The patient made an uneventful recovery and left the hospital on the 23rd. The growth was examined by Dr. Rolleston who pronounced it to be an epithelioma. The patient was last seen in May, 1904, and was well and free from recurrence.

CASE 9.—A woman, aged 48 years, was admitted into the Cancer Hospital on August 18th, 1903, under the care of Mr. W. E. Miles. For three weeks she had noticed a sore place on the tongue, but for 14 years she had had "minute ulcers all over the tongue." 12 years ago "a tooth rubbed against the tongue" on the left side far back, but the tooth was removed. For 12 years also she had noticed white patches on the tongue. The patient had had two miscarriages but there was no other history of syphilis. On examination, far back on the left margin of the tongue was a warty ulcer surrounded by a small amount of induration. The dorsum was covered with leukoplakia. On the 19th a snip of the growth was removed for microscopical examination. The report was "rapidly growing epithelioma." The patient at first refused to have the tongue removed but ultimately accepted and the left half and the submaxillary glands were excised. On Nov. 14th there was no sign of recurrence.

CASE 10.—A woman, aged 42 years, was admitted into the Cancer Hospital on April 11th, 1904, under the care of Dr. F. A. Purcell. For three years she had noticed a growth on the tongue which had given her no trouble except for some slight pain lately. She thought it was caused by her artificial teeth. No history of syphilis was obtained. On the dorsum of the tongue, half an inch from the tip and extending from just internal to the right edge for three-quarters of an inch across the dorsum, was an oval ulcer about one and a quarter inches long; the edges were somewhat raised and the base was irregular and sloughy. There was very slight induration around and the edges were not hard or craggy. The tongue was freely moveable, the floor of the mouth being unaffected; there were no enlarged glands to be felt. On the 13th the right anterior half of the tongue was removed and an uneventful recovery followed.

In conclusion, I am much indebted to those surgeons who have kindly allowed me to publish their cases.

Wimpole-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

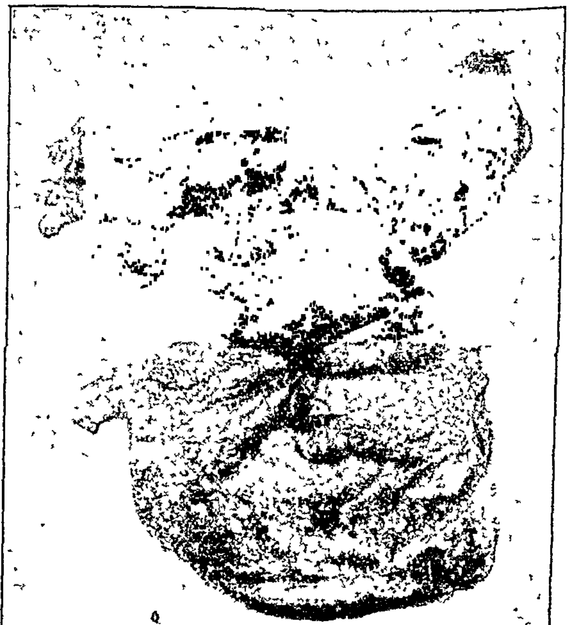
A RARE FORM OF INTESTINAL STRANGULATION.

BY R. H. STEEN, M.D. LOND.,
SENIOR ASSISTANT MEDICAL OFFICER TO THE WEST SUSSEX COUNTY ASYLUM, CHICHESTER.

THE patient, a married woman, aged 49 years, was admitted into the West Sussex County Asylum on June 25th, 1901, suffering from chronic mania. She was quiet as a rule and had fixed delusions. Physically she was of moderate health and had slight mitral regurgitation. On Jan. 13th, 1904, she was seized with an attack of influenza, then epidemic in the institution. The symptoms were chiefly of the gastric type, with vomiting, slight pyrexia, muscular pains, and headache. She was better on the 16th and took her food well. On the 17th there were slight abdominal pain and distension which increased during the day. She was able to retain the greater portion of her food though slightly sick in the evening. On the 18th the tympanites became greater and she vomited all food. The vomit was not fæcal in character. She died on the afternoon of the 19th.

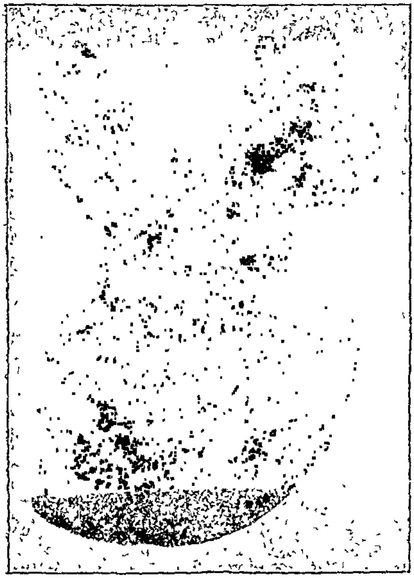
At the post-mortem examination the stomach and small intestine were found to be distended by gas. In the right iliac fossa the following condition was found. A volvulus had been formed by the terminal portion of the small intestine and through this the cæcum with the vermiform appendix had passed in the form of a loop. An internal hernia of the

FIG. 1.



Anterior view, showing the loop of the cæcum with constriction formed by a knot composed of small intestine.

FIG. 2.



Posterior view of the same.

large intestine had thus been produced, the constricting portion being the small intestine. The digestive tube had thrown itself into a slip-knot and it is difficult to imagine how this extraordinary state of affairs could have been produced. The attachments of the cæcum were probably *loose in character, which may have accounted for two* previous attacks of abdominal pain and tympanites which she had had in 1901, but the knot described must have been of recent formation, as no signs of plastic peritonitis were evident.

Chichester.

THE TREATMENT OF TETANUS BY INTRAVENOUS SALINE INFUSIONS.

BY VINCENT S. HODSON, M.B., B.CH. OXON.,
LATE RESIDENT MEDICAL OFFICER AT THE KASR-EL-AINI HOSPITAL, CAIRO.

IT seems to me worth while recording some fairly successful cases of tetanus treated by the above method inasmuch as the ordinary methods—viz., antitoxin, chloral, and bromide—are far from satisfactory, and though my cases are only three in number yet the immediate result was so striking that I feel encouraged to send them for publication.

CASE 1.—The patient was an Egyptian fellah who had had masseter spasm for 12 days before admission to the Kasr-el-Aini Hospital, Cairo. He was treated vigorously with antitoxin for the first two days in hospital, but as his condition seemed to me to get worse I on purely empirical grounds bled him 15 ounces and infused two kilogrammes of normal saline solution containing 75 grammes of brandy under complete surgical anæsthesia. Before his recovery from anæsthesia I gave him a dose of antitoxin and injected half a grain of morphine subcutaneously. After very profuse sweating he slept quietly and when I saw him next day had only very slight spasm of the masseters, which disappeared in a few days.

CASE 2.—This was a case of acute tetanus following on a tramway accident in which the patient lost both legs in the neighbourhood of the knees. About a week after admission to hospital tetanic spasms came on and when these had lasted five days and the patient's condition was very serious I heard of the case and with the permission of Mr. F. C. Madden, to whom I am indebted for this case, I infused him, bled him, and injected serum and morphine as in Case 1. This was followed by sleep for eight hours and complete cessation of spasm until about 4 A.M. next morning, that is, 16 hours in all. Spasm, however, returned with great rapidity and so I infused him again with the same result, but death ensued 24 hours later. This case was rather a severe test, as the man was quite young and very poorly nourished and was recovering from a very severe accident. The origin in this case was thought to be in a stitch which suppurated for a few days and then healed under treatment.

CASE 3.—This case was very similar to the first one and, as in that case, there was no history of wound. This absence of history is not to be wondered at as the fellaheen, for the most part, do not know their own ages and have practically no powers of memory or observation. Seven days of increasing spasm was the history obtained and shortly after admission to hospital I infused him with two kilogrammes of saline solution and 75 grammes of brandy and gave him the same injections as in the other cases. With the exception of *very slight masseter spasm next day there was no return of* symptoms and the patient was discharged after a short stay in hospital quite well.

Though not claiming that this treatment is a certain cure, the record of the above cases shows that it undoubtedly exercises a profound influence on the condition of spasm, and if added to the treatment of tetanus recommended in THE LANCET of August 6th, 1904, p. 386, will, I hope, help to reduce the present very heavy mortality that is quoted by the authorities.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.

A CASE OF TRAUMATIC TETANUS WHICH RECOVERED UNDER TREATMENT BY HYPODERMIC INJECTIONS OF CURARE.

(Under the care of Mr. W. J. SYMES.)

FOR the notes of the case we are indebted to Dr. J. H. Connolly, house surgeon, and Dr. W. B. Cullen, assistant house surgeon.

On June 12th, 1904, a youth, aged 16 years, was admitted to the Chesterfield and North Derbyshire Hospital, with the history of having had his right leg crushed by the wheel of a wagon while at work in a coal-pit on June 3rd, causing a superficial ragged wound, about two by one and a half inches, in the popliteal space He was taken home and seen the same evening by Mr. J. A. Magee of Clowne, near Chesterfield, who dressed the wound which progressed satisfactorily until the 10th when the patient was seized with spasm of the muscles of the neck and jaw, followed by difficulty in swallowing. A diagnosis of tetanus was made and Mr. Magee gave two injections of antitetanic serum, ten cubic centimetres each, before sending him to the hospital on the 12th.

On admission at 2 P.M. there was found marked rigidity of the muscles of the jaw, neck, and abdomen. He was unable to separate the teeth, risus sardonicus was present to some extent, and he was sweating profusely. The temperature was 99·8° F., the pulse was 88, and the respirations were 32. He was put to bed, ten cubic centimetres of antitetanic serum were injected subcutaneously at 4.30 P.M. the same evening, the wound was thoroughly cleansed, and a carbolic compress, 1 in 40, was applied and changed every four hours. He continued much the same till June 14th, when he had a tetanic convulsion at 4.45 P.M. and ten cubic centimetres of serum were injected at 6.30 P.M., to be followed at 8 P.M. by another attack. The spasms were controlled by chloroform. Between midnight on the 14th and 5 A.M. on the 15th, at intervals of rather less than an hour, the patient had seven very severe tetanic seizures, in some cases with opisthotonos, during which respiration was seriously interfered with, and chloroform was freely administered, artificial respiration being resorted to during the worst attacks. Bromide and chloral given per rectum produced no apparent benefit.

Any attempt to feed the patient or to touch him at this period brought on a spasm and he was therefore left as quiet as possible till at 5.15 P.M., June 15th, on trying to pass a nasal tube for feeding purposes, another violent convulsion was induced. He was again anæsthetised and 30 grains of chloral hydrate were passed by the stomach tube. This was retained and the patient slept quietly for several hours. He felt better on waking and was able to take liquid nourishment by the mouth but was unable to separate the jaws. He continued to be more comfortable until 2 P.M. on the 16th, when he had a slight spasm from turning himself in bed. He was given 15 grains of chloral hydrate by the mouth and was quiet again till 1 A.M. on the 17th, when he had another slight spasm for which a similar dose was administered. The highest temperature recorded was on the 15th when it reached 101·6° F. at 2 P.M. The pulse was 104. The patient sweated profusely during the attacks and thirst was extremely marked. The wound was now dressed with a strong solution of sanitas in the hope of inhibiting the development of fresh organisms.

On June 19th it was decided to try curare and at 6 P.M. one-twelfth of a grain was given subcutaneously. He had a spasm at 1 A.M. on the 20th, for which a further one-twelfth of a grain was injected at 1.20 A.M., after which he remained free till 8.45 A.M., when another seizure took place for which he was given 20 grains of chloral hydrate at 8.55 A.M. At 4.40 P.M. a fresh attack came on and curare, one-sixth of a grain, was injected at 5.40 P.M. He had a slight spasm at 8.30 P.M. and again at 8.45 P.M. 30 grains of chloral hydrate were given by the stomach tube under chloroform. At 9.15 P.M. ten cubic centimetres of serum were injected, but another sharp spasm came on at 11.15 P.M., followed by slight attacks at intervals of about two hours, until at 5 P.M. on the 21st he had a very severe convulsion, which as usual was controlled by chloroform. A similar event occurred at 1.10 A.M. on the 22nd and one-third of a grain of curare was injected at 1.15 A.M. Except for the constant state of rigidity of the muscles he was now fairly comfortable. Slight spasms manifested themselves at 4.40 and 4.50 P.M. on the 22nd and at 6.5 P.M. he was given half a grain of curare. At 10.20 P.M. 30 grains of chloral hydrate were administered by the stomach tube under chloroform to induce sleep and at 1.35 A.M. on the 23rd two-thirds of a grain of curare were injected. The patient felt better after this, the jaws could be separated slightly, and he was free from spasms, but as a precautionary measure five-sixths of a grain of curare were injected at 1.15 A.M. on June 24th with steady improvement and the same night at 8.20 one grain of curare was given. The temperature this day was 100·4°, the pulse was 120, and the respirations were 54. The teeth could now be separated fully a quarter of an inch and in order to see whether any change would occur the curare was discontinued. June 25th passed uneventfully, but at 6.30 P.M. on the 26th another severe convulsion made its appearance, with close apposition of the teeth once more. At 6.45 P.M. one grain of curare was injected and the same dose was repeated at 1.35 A.M. on the 27th without recurrence of spasm. The jaws could again be separated as before and accordingly curare was continued once every 24 hours in increasing doses up to two and a half grains at 1.30 A.M. on July 1st, when very marked improvement set in. From this date a daily administration of one grain of curare was kept up until the 9th, when he was able to use his jaws to masticate food, and then half a grain till the 20th, with steady reduction in the tonicity of the muscles. Active treatment was discontinued after July 20th, he developed an excellent appetite, and put on flesh rapidly. The patient was placed out-of-doors on June 27th in a recumbent position to have the advantage of the bright sunshine and daily afterwards when weather permitted. A month after the onset of tetanus he was able to walk about and on August 13th he left the hospital quite well.

Remarks by Dr. CONNOLLY and Dr. CULLEN.—The case presents some features of interest, viz.—(*a*) Incubation period (seven days). Some recent statistics have placed the mortality at 96 per cent. in cases where tetanus manifests itself under ten days after injury. (*b*) Number of spasms: 16 severe and 14 less severe, 30 altogether. (*c*) Marked improvement under treatment with curare and recurrence of the spasms when it was stopped during the active stage of the disease. In all $26\frac{2}{3}$ grains of curare were given hypodermically. No ill effects on the heart were observed and the patient said that he felt more comfortable and could breathe more easily after the injections.

Mr. W. J. Symes, under whose care the patient was admitted, has kindly permitted us to record these notes.

WEST CORNWALL MINERS' AND WOMEN'S HOSPITAL, REDRUTH.

CASES OF ABDOMINAL SECTION PERFORMED FOR INTUSSUSCEPTION AND PERFORATING GASTRIC ULCER.

(Under the care of Dr. JOHN H. TONKING.)

IN these cases, which were three in number, one patient suffered from intussusception and the other two from perforating gastric ulcer. The case of intussusception terminated fatally; of the other two patients one recovered and the other succumbed on the eleventh day after an operation for subphrenic abscess. Including these, three operations for perforation, all performed by Dr. Tonking, have taken place at this hospital during the last 12 months.

CASE 1.—The patient was a man, about 40 years of age, who was seized with acute abdominal pain on Jan. 18th. There was great tenderness equally in the appendicular region and in the epigastrium and hot opium fomentations were applied at 1 P.M. At 6 P.M., as no relief was felt, a consultation was held with Dr. Frank Hichens of Redruth, when perforation was diagnosed, and as the man's wife admitted having had considerable difficulty with regard to his food the perforation was considered to be probably in the wall of the stomach, although there was marked appendicular tenderness. The liver dulness was normal and there was no vomiting; the abdomen was absolutely rigid and typical facies was present. At 9 P.M. ether was administered by Dr. William Blackwood and assisted by Dr. Hichens Dr. Tonking opened the abdomen. Gas immediately escaped and a perforation was found at the pyloric end of the stomach close to the lesser curvature. The abdomen was swabbed but no irrigation was used as there was no extravasation. The position rendered tucking in difficult, and partly by turning in and partly by stitching the omentum over the perforation was closed by a double layer of fine silk sutures. A drainage-tube with a gauze wick leading to the perforation was placed in the wound after swabbing the parts dry without irrigation and the wound was closed. The usual rectal feeding was employed for five days with the addition of strychnine when required. The temperature, however, did not come down but remained between 100° and 101° F. for a week when dulness was discovered at the right base. This increased and on the tenth day, after exploring with a needle in the ninth interspace, pus was let out by excising a portion of the tenth rib. The temperature still did not come down and the patient died on the next day. There were no stomach symptoms and the abdominal wound had practically healed.

CASE 2.—The patient was a youth, aged 19 years. He was staying in Camborne for Easter Monday and after dinner was walking in the town when he was seized with agonising pain in the abdomen for which each of his friends suggested a different variety of spirit. After taking whisky, brandy, rum, and gin without relief he was put into a cab, in the bottom of which he lay doubled up, and was in this way taken home. Dr. Tonking was informed that he had suffered for months from distress an hour or more after meals. The abdomen was board-like. There was repeated vomiting of material having a spirituous odour. The liver dulness was normal. The patient was removed to the hospital and after arrival there the liver dulness was found to have disappeared. At 8 P.M.—namely, five hours after the attack—ether was administered by Dr. Blackwood and Dr. Tonking, assisted by Dr. Hichens, opened the abdomen. There was an immediate escape of gas and a small perforation of the size of a pea, which was found near the pylorus at the lesser curvature, was tucked in and fixed by two rows of silk sutures. The t[illegible]perature at the time [illegible] day it was 102°, an[illegible]adually to normal b[illegible] employed, together [illegible] On the fifth day gradually increasing quantities of food began to be given. The drainage tube was removed on this day and recovery was uneventful. Calomel was given on the fourth day. After one month of milk, plasmon jelly, and similar diet *solid food was gradually given. The patient left the hospital* after six weeks with no gastric symptoms.

CASE 3.—The patient was aged 11 months and was seized on May 18th with pain in the abdomen like colic. The child was nursed by the mother and a little Mellin's food was given as well. The patient was seen by a medical colleague and the condition was treated by him as colic. On the third day, during the absence of this practitioner, Dr. Tonking was called in and found a child who for three days had been suffering from paroxysmal pain and for the last 24 hours there had been a blood stained mucoid anal discharge. Per anum a tumour could be felt, the contour of which was suggestive of the cervix uteri. No abdominal tumour could be felt, the abdomen was distended. On the same day (May 21st) the child was admitted into the hospital where ether (Rendle's mask) was administered by Dr. Blackwood and the case was examined with the assistance of Dr. Hichens. No tumour could be felt a circumstance which was attributed partly to the child being fat and well nourished and partly to the abdominal distension. The abdomen was opened in the middle line and as it was found impossible to deal with the intussusception a cross cut was made towards the left side. After this the intussusception was readily reduced, in fact, on the least pressure it ran up the intestine like a mouse creeping on until within the last six inches, after which every effort (even pressure to partial rupture of the peritoneal coat) failed to reduce it. As reduction was impossible the [illegible] found to be [illegible]on was excised [illegible] the returning [illegible], however succumbed to the operation owing to the length of time involved and to the unfortunate delay in recognising the condition. The intussusception was of the ileo cæcal variety, the apex being the ileo cæcal valve.

Remarks by Dr. TONKING.—The last case shows the ease of reduction of an intussusception up to a certain point and the uselessness of water or air injection to deal with the last few inches in an intussusception if there is any marked swelling. It likewise demonstrates the ease of reduction if such cases are recognised at once.

Reviews and Notices of Books.

The Examination of Waters and Water Supplies. By JOHN C. THRESH, D.Sc. Lond., M.D. Vict., D.P.H. Cantab. London: J. & A. Churchill. 1904. Pp. 460. Price 14*s.*

THE value of chemical and bacteriological analysis respectively in regard to the determination of the purity of water supplies has been doubted by various observers from time to time. The first opponents to bacteriological analysis were generally the old school of analytical chemists who pinned their faith to chemical methods. On the other hand, not a few bacteriologists at one time looked upon the chemical analysis of potable waters as without value. The fact is that both chemical and bacteriological methods have their discrepancies and this view has now come to be shared by all concerned. There are instances in which it has been known that slight contamination of a water has taken place and yet chemical analysis has given practically negative results, while organisms of the colon series were readily detected by bacteriological methods. Owing to the splendid investigation that has been directed to the isolation and recognition of the flora of sewage it would seem that the detection of pollution so slight as 1 part per 1,000,000 can be effected by bacteriological means. On the other hand, if a considerable time has elapsed since the pollution took place the recognition of impurity by bacteriological processes becomes uncertain. The same applies to chemical analyses, though in this instance, in spite of purifying influences at work, the products of combustion, so to speak, may be found. Thus nitrogen previously existing in organic matter and ammonia may be ultimately present as nitrate. In surface water it is certain that ammonia and nitrites are scarcely ever present to any extent without sewage contamination. Valuable as may be the indications given in a carefully conducted chemical analysis, one very important fact must ever stand out in favour of bacteriological examination and that is that in the case of filtered supplies the purifying work of the filter bed is essentially bacteriological and therefore the efficiency of the filter bed can only be controlled by instituting bacteriological analyses of the effluent. Dr. Thresh has had the advantage of considerable practical experience with both methods of analysis and in his book on the subject he sees no reason for abandoning chemical methods. "In recent years," he says, "bacteriology has come to the aid of chemistry, and there is now a general opinion that a bacteriological examination is more important than a chemical analysis. This is undoubtedly true in some cases but not in all. A properly made bacteriological examination may often afford indications of pollution which no chemical analysis could possibly detect, but I am afraid that the inferences drawn from the results of many so called bacteriological examinations are often as fallacious as those derived from the results of chemical analyses. When we find that waters used for long periods by large communities are condemned by bacteriologists as being dangerously polluted, and that the results obtained from the same water by different bacteriologists differ to an extent which is impossible in a chemical analysis, our faith in bacteriological examination is somewhat shaken. In any case a proper bacteriological examination is far more tedious and more troublesome to perform than a chemical analysis, and the results are even more difficult to correctly interpret." He very properly, however, emphasises the importance of making a microscopical and biological examination of suspended matter in drinking water for "very often such an examination reveals more quickly and certainly the character of a water and some defects in its source than either a chemical or bacteriological analysis. In several instances such an examination has led to the discovery of sources of pollution which had been overlooked at a careful inspection."

Dr. Thresh's remarks upon the importance of making careful inspection of the source of supply should be very carefully considered by those engaged in analysis. Often the examination of the source of supply has given him far more important information than could be obtained from the analytical results. The examination of the source in numerous instances in which the supplies were the cause of outbreaks of disease was the means of affording information without which the chemical, bacteriological, or microscopical examination of the water "could not have been correctly interpreted." Part I. of his book, since it deals with the examination of the sources from which the water is derived, is therefore of the greatest importance. In Part II. the various methods of examining water and the interpretation of the results are very thoroughly considered and in Part III. the analytical process and methods of examination are set forth in practical detail. The chapter on Bacteriological Examination of Water will serve as an eminently practical guide to the bacteriologist. Dr. Thresh has wisely kept within the limits of the application of bacteriology to the differentiation of pure from polluted waters and points out concisely and clearly the lines upon which it is safe to proceed. In choosing this course he is supported by the evidence

LIBRARY TABLE.

Manual of Midwifery. By W. E. FOTHERGILL, M.A., B.Sc., M.D. Edin. With double Coloured Plate and 86 Illustrations in the text. Third edition. Edinburgh: W. F. Clay. 1903. Crown 8vo. Pp. 506. Price 9*s.* net.—Dr. Fothergill has succeeded in revising this edition of his book on midwifery without increasing its bulk, so that it retains its former convenient size. The chief alterations are to be found in the description of the development of the membranes and placenta in which the work of Spee and Peters is included. The whole of this chapter has been rewritten and it now contains a very good account of the development of the early ovum, illustrated by numerous drawings, mainly taken from Whitridge Williams's book on "Obstetrics." Besides this we note that a short description of chorion-epithelioma has been added and the author brings forward his view that "the function of the decidual cells is to destroy chorionic epithelium when the latter unduly invades the maternal tissues in contact with the ovum." The ovum is a parasite whose external cells exercise a phagocytic action upon the superficial portion of the decidua. But the decidua resists invasion by producing the decidual cells, which in their turn have a phagocytic action upon the chorionic epithelium. Failure on the part of the decidual cells to exercise this function may be supposed to allow of the admission of fragments of living chorionic epithelium into the maternal tissues. Dr. Fothergill does not approve of Bossi's dilator; when the cervix is softened dilatation by the finger is, he says, easy, and when the cervix is unsoftened Bossi's dilator is slower, more uncertain, and probably more unsafe than the use of multiple incisions. We cannot agree with him in these views. It is a pity that he should perpetuate the use of the inaccurate term "hydatid mole." There is no reference in the index to deciduoma malignum and the binding of the book leaves much to be desired. As we have said of former editions, however, the manual is a good one, clearly and well written, and we can recommend it to students.

On the Classification and Pathology of Beri-beri. By HAMILTON WRIGHT, M.D. McGill. London: John Bale, Sons, and Danielsson, Limited. 1903. Pp. 74. Price 3*s.* 6*d.* net.—The author of this work first devotes a page to a recapitulation of his previous papers on the subject, in which he endeavoured to show that the incubation period of the disease is short—from seven to 14 days; that it is an acute or subacute infectious disease due to a specific organism not yet certainly determined; that the organism is not one whose special habitat is any food such as fish or rice but one that may, nevertheless, be ingested in any food and drink accidentally contaminated; that the organism multiplies in the contents of the stomach and small gut; and that it there elaborates a toxin which, being absorbed, poisons certain neurons and thus gives rise to a group of symptoms which can be classified. In the book now under notice the author discusses more fully the classification and pathology of beri-beri. He endeavours to make it clear that there is not only clinical evidence but also indisputable post-mortem evidence that beri-beri must be regarded as an acute infectious disease having a definite primary lesion. He proposes the following classification: (1) acute pernicious beri-beri, in which the onset is sudden, with more or less severe symptoms of gastro-duodenal irritation and cardiac paralysis; (2) acute beri-beri, in which the onset is sudden, though never so sudden as in acute pernicious beri-beri, with more or less noticeable symptoms of gastro-duodenal irritation and concomitant vaso-motor and sensori-motor paresis; (3) subacute beri-beri, in which the onset of the disease is more insidious, in which the gastro-duodenal irritation may escape notice and in which the paresis may be so slight as to involve only one or two movements, a few areas of sensation and the vascular supply to the front of the legs; and (4) beri-beri residual paralysis or neuritis, or the disease as it appears after the symptoms of gastro-duodenal irritation have disappeared and after the causal organism and its toxin have accomplished their work and have been eliminated. A report of observations made both clinically and post mortem in each of these classes of cases of beri-beri follows and 17 cases are given in clinical and pathological detail in support of the classification. The book is illustrated by three plates (two coloured); there is also a useful table of references. The author draws attention to the fact that the mode of action of the causal organism of beri-beri presents some analogy to that of diphtheria.

Census of India, 1901. Vol. I. Ethnographic Appendices, being the Data upon which the Caste Chapter of the report is based. By H. H. RISLEY, I.C.S., C.I.E. Calcutta: Office of the Superintendent of Government Printing, India. 1903. Pp. 251. Price Rs.3 or 4*s.* 6*d.*—This volume contains in the form of appendices the principal data upon which the caste chapter in the first volume is based. In accordance with the order of treatment adopted in that chapter the physical evidence has been set out first. It consists of summaries of measurements and diagrammatic seriations of the data which serve to establish the types. The data are the proportions of the head, proportions of the nose, relative prominence of the root of the nose, and the stature. Appendix II. deals with the social grouping of the different tracts of country. Appendix III. consists of maps—a general map locating the main physical types and a number of small maps illustrating the distribution of the more important tribes and castes. Appendix IV., which occupies the greater part of the volume, comprises a number of accounts, derived from various sources, of some typical tribes and castes of the various ethnic regions. The selection has been made with the object of covering as much ground as possible and giving within a moderate space, yet in fairly full detail, a description of some of the chief constituent elements of the population of India. The last appendix, No. V., deals at length with the "Modern Theories of Caste." It is by Mr. J. C. Nesfield, Sir Denzil Ibbetson, K.C.S.I., and M. Emile Senart. The theories of these observers have already been referred to in the main chapter. Sir Denzil Ibbetson gives at some length what seems to him the fundamental ideas upon which caste is based. His theories have already appeared in the census report of the Punjab for 1881. The whole volume is an interesting one and will repay the student of ethnology for the time expended in its study.

JOURNALS AND MAGAZINES.

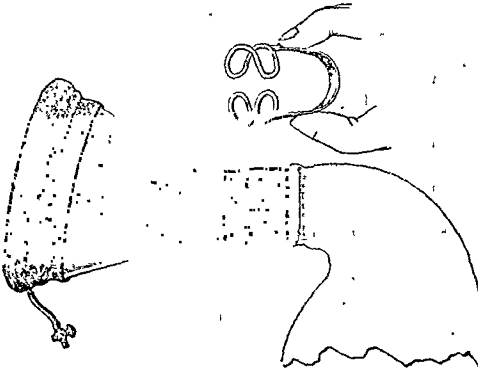
The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., F.R.S., and J. N. LANGLEY, F.R.S. Vol. XXXI., No. 5. London: C. J. Clay and Sons. August 22nd, 1904. Price 8*s.*—The articles contained in this number are as follows: 1. The Influence of Changes in the Intraocular Circulation on the Intraocular Pressure, by E. E. Henderson, F.R.C.S. Eng., and E. H. Starling, F.R.S., with nine figures in the text. The authors show that the intraocular pressure in cats and dogs, which were the animals experimented on, is a function of the blood pressure in the ocular blood-vessels and varies directly with this. Stimulation of the cervical portion of the sympathetic causes first a rise and then a fall of intraocular pressure, the former effect being due to contraction of the orbital unstriated muscle, the latter to contraction of the intraocular blood-vessels. Stimulation of the peripheral end of the divided fifth nerve root causes a rise of pressure due to contraction of the orbital unstriated muscle; this effect was absent after extirpation of the superior cervical ganglion and degeneration of the fibres passing from it to the Gasserian ganglion. There is no evidence of the presence of vaso-dilator fibres either in the fifth or in the sympathetic nerves. The effects of adrenalin and nicotin on the eye vary with the preponderance of local or general effects on the blood-vessels. 2. The Influence of Fasting and Feeding upon the Respiratory and Nitrogenous Exchange, by M. S. Pembrey, M.D. Oxon., and E. I. Spriggs, M.D. Lond. This article gives the results of numerous experiments on the metabolism of the body in rats during successive periods of fasting and feeding. 3. The Protective Value of Proteids and their Decomposition Products on Trypsin, by H. M. Vernon, M.D. Oxon. The method employed was to expose a known percentage of the substance for one hour at 38°C. to pancreatic extract with 0·4 per cent. of sodium carbonate and then to determine the amount of trypsin destroyed. Dr. Vernon finds that when no proteid is present 56 per cent. of the ferment is destroyed, but only 7 per cent. in presence of 4 per cent. of proteid. 4. On the Action of Oxygen at Low and High Pressure upon the Corneal Endothelium, by G. Bullot, assistant in physiology at the University of California, with eight figures in the text. The figures show the curious differences which result in the vitality of the endothelium after enucleation and scraping off the epithelium from the cornea, loss of vitality commencing at the periphery and proceeding towards the centre with low pressures and in the opposite direction with high pressures. 5. The Union of Different Kinds of Nerve Fibres, by J. N. Langley, F.R.S., and H. K. Anderson, M.D. Cantab. 6. The Elasticity of Animal Tissues, by J. B. Haycraft, M.D., with 23 figures in the text. Dr. Haycraft finds that all of the simple tissues of the body follow Hooke's law when they are stretched within physiological limits. The relaxing appears to vary and Hooke's law is not always observed. 7. On the "Sham Death" Reflex in Spiders, by T. Brailsford Robertson, with one figure in the text. Mr Robertson finds that with the nervous system intact "sham death" is a complete tetanus and is not due to the conscious volition of the animal, but is a reaction necessarily consequent on the structure of its nervous system. In some species it can be carried out by the thoracic segments alone, in others the head ganglia require to be intact. 8. On Autogenetic Regeneration in the Nerves of the Limbs, by J. N. Langley, F.R.S., and H. K. Anderson, M.D. Cantab. The experiments of these observers, so far as they go, are decidedly in opposition to the autogenetic theory. This number of the journal also contains the Proceedings of the Physiological Society.

The Phonographic Record, September, 1904.—In this issue the lecture by Sir W. R. Gowers on Chorea and its Neuronic Aspect is concluded. The lecturer states that "if we grasp the idea that multiplicity is the equivalent of size, and that common function involves a common constitution, identical through a vast series of minute structures, and also a common liability to suffer from the same influences, much of the difficulty of conceiving chorea as a dendritic disease will disappear." Mr. Norman Porritt describes chloride of ethyl as the anæsthetic *par excellence* for minor operations and discusses a form of apparatus made by Messrs. Down Brothers at his suggestion for the administration of the drug. Dr. E. B. Gray has written a note on a variety of kidney (a single kidney of double size) found at the post-mortem examination on a woman who had been run over. Another note relates to the case of a woman, aged 63 years, who left off eating fruit and vegetables for 12 months because she had "suffered from indigestion" and at the end of that time had well-marked scurvy, which was cured by five weeks' remedial feeding in hospital.

New Inventions.

A NEW INHALER FOR ETHYL CHLORIDE.

THE accompanying illustration shows a modified form of wide bore ethyl chloride inhaler. As there is no lint in the face-piece the patient's face can be seen throughout the administration. The neck of the bag fits over that of the face-piece and can be freely rotated about it. Corresponding openings are made in the inner and outer necks and when these coincide the anæsthetic can be sprayed through them into the bag. Within the neck of the face-piece is a bit of lint fixed (opposite the aperture) by a clip so as to form a pocket which is open towards the bag; just as an aortic valve forms a pocket open towards the aorta. The lint minimises reflux of the spray into the face-piece and economises the anæsthetic. When a gag is used the inhaler can be applied *uncharged* the moment the gag is adjusted and then can be charged during a convenient expiration. After a breath or two the air-way is closed by slightly rotating the neck of the bag. This inhaler is especially useful in dealing with the large numbers of children met with in hospital practice, as about 18 cases of adenoids and tonsils can be operated upon per hour when anæsthetised as described. The inhaler is made by Messrs. Allen and Hanburys, with one face-piece, for a guinea. A smaller size face-piece can be supplied, the two sufficing for all cases.



Burwood place, W. A. BERESFORD KINGSFORD.

A NEW INGUINAL COLOTOMY BELT AND A MODIFIED HERNIA TRUSS.

A VARIETY of expedients have been adopted for securing the dressings and coverings requisite in the treatment of colotomy. Some of these are, no doubt, more successful than others and I find that an inguinal colotomy belt, which has been made at my request, fulfils all requirements. The usual indiarubber bag or pouch has been dispensed with and replaced by a wire vaccination shield affixed to a light abdominal belt, which is well shaped to grip the pelvis. The shield is lined with the ordinary green protective and can be filled with absorbent tow or wool, either carbolised or charged with charcoal, thus providing a cleaner and more efficient method of dealing with the fæces than the usual pouch. In order to prevent the belt slipping upwards and so displacing the receptacle buttons are sewn along its lower border and these fix it to tightly fitting bathing drawers or pants furnished with button holes and drawn up over the belt. In this way perineal bands are avoided and great comfort is obtained. In my earlier cases of colotomy the belt was always a trouble [illegible] hs are due to Messrs. [illegible] ited, Victoria-bridge, [illegible] tions and producing a [illegible]

The sa [illegible] ule a specially soft and flat pad for hernia trusses.

HERBERT LUND, F.R.C.S. Eng.

St. John-street, Manchester.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 17, 1904.

Uncertified Mental Incapables.

We have already referred to the fact that, to quote the official announcement, "the King, on the recommendation of the Home Secretary, has been pleased to appoint a Royal Commission to consider the existing methods of dealing with idiots and epileptics and with imbecile, feeble-minded, or defective persons not certified under the lunacy laws; and, in view of the hardship or danger resulting to such persons and the community from insufficient provision for their care, training, and control, to report as to the amendments in the law or other measures which should be adopted in the matter, due regard being had to the expense involved in any such proposals and to the best means of securing economy therein." In an age remarkable for its spirit of inquiry and investigation and for an abounding philanthropy it is not surprising that the Home Secretary, as the public official mainly responsible for the internal well-being of the community, has at last been impressed with the total inadequacy of the provision made for dealing with the enormous class of mental incapables who, not being certified lunatics, are unfit either to earn a livelihood or to look after themselves or their affairs. Whether these weaklings are merely idle and mischievous vagrants or unsightly and unwholesome domestic burdens, liable to suffer neglect and ill-treatment, or whether they have active criminal tendencies themselves or show an aptitude for crime as tools in the hands of others, they are all more or less a public evil and a source of trouble, anxiety, and danger. They may be said to be "no good to anybody" and it is fitting that the State, standing *in loco parentis*, should, by appointing a Royal Commission on the subject, indicate its responsibility with regard to every member of the community who is, by nature or from disease, idiotic, epileptic, imbecile, feeble-minded, or defective, but not certified under the lunacy laws.

The reference under which the Commission is to act is no doubt a comprehensive one but if we understand it aright it appears to us to be framed so as to exclude the consideration of at least two groups of cases of mental disorder or defect as to the treatment and management of which the public would be glad to have a pronouncement by a Royal Commission after full inquiry. The first group consists of those cases of mental incapacity arising from incipient or oncoming insanity taken at the time when the questions of certification and protective supervision have to be decided. Evidence given before a Royal Commission would be of the utmost value when, if ever, the proposed legislation on this matter comes up for consideration in Parliament. We are willing to admit that this group does not appear to come immediately within the scope of the reference and its omission may be due to a supposed irrelevancy and to the fact that the Bill dealing with it is in the hands of the Attorney-General and his department. The other group of cases consists of the many certified lunatics in asylums who by reason of the chronicity of their disease have degenerated into simple harmless imbeciles corresponding to all intents and purposes with the uncertified imbeciles whose case is to be considered by the Commission. These men and women have accumulated in all our public asylums to such an extent that they are largely the cause of the indefinite expansion of those institutions. We think that it will scarcely be possible for the Commission so to frame its report as to exclude a *modus vivendi* other than the lunatic asylum for this class of imbecile. At all events, any provision of an economical sort made by the Commission for the imbeciles included in its reference will not unjustifiably have to be considered by asylum authorities with a view to the possible discharge of their harmless imbecile population.

The work of the Commission is comprised under two heads—viz., to consider the existing methods of dealing with uncertified mental incapables and to report as to the amendments in the law or other measures which should be adopted in the matter—and we are convinced that most useful and valuable information will be derived both from the evidence and from the report. The Commissioners will have their highest aspirations somewhat curtailed by the rider to the reference which intimates that due regard is to be had "to the expense involved in any such proposals and to the best means of securing economy therein." Their proposals will perforce lie between the Scylla of legislative enactment involving questions of personal liberty and an annual grant and the Charybdis of economy with due provision for control, maintenance, and supervision. We have no fear that, if the Commissioners are able to make out a case, the public will be otherwise than willing to ratify their recommendations in a matter in which the best and healthiest interests of the community are involved. The following is the constitution of the Commission: the Marquis of Bath (chairman), Mr. William Patrick Byrne, C.B., Mr. Charles Hobhouse, M.P., Dr. Frederick Needham, Mr. Henry David Greene, K.C., M.P., Mr. Charles Edward Heley Chadwyck-Healey, K.C., the Rev. Harold Nelson Burden, Mr. Willoughby Hyett Dickinson, Mr. Charles Stewart Loch, and Mrs. Pinsent. The names of the Commissioners are a guarantee that the work will be thoroughly and efficiently carried out. But in a matter so largely of medical import in the domain of mental hygiene we may be pardoned if we take the liberty of pointing out that while the terms of the reference explicitly exclude the area covered by the lunacy laws the only medical man on the Commission is Dr. Needham, the whole of whose life has been spent in the administration of those laws either as an asylum superintendent or a Commissioner in Lunacy. In view of the remarks which we have made with regard to the scope of the inquiry it will readily be understood that we look upon Dr. Needham's appointment on the Commission as most fitting and proper, but several names occur to us, as they will to others, of men of vast medical experience, not necessarily official, among the classes under consideration any one of whom might have been selected and appointed as a member to act with him as a professional colleague in examining the witnesses and in dealing with the evidence submitted on a subject so full of intricacy and responsibility.

Infantile Diarrhœa.

DURING the late summer and early autumn months the mortality due to gastric and intestinal affections in infants is always high and this year in certain towns the number of deaths has been unusually large. This fact has been commented on by our correspondents in Ireland and Liverpool.[1] At the meeting of the Dublin public health committee held on August 16th the death rate for the previous week was reported to be 28·1 per 1000 and of this large mortality no less than five deaths in every 1000 were due to diarrhœa. At the meeting of the Liverpool health committee held on August 18th attention was also drawn to the prevalence of diarrhœa and the high death rate of the city for the previous two weeks, which had reached the figure of 37·7 per 1000.

Diarrhœa is essentially a symptom dependent on various morbid causes. In infants it is most frequently the consequence of inflammation brought about by the direct irritation of the intestinal mucous membrane by improper feeding. One of the most important etiological factors concerned in this affection is undoubtedly the ignorance of the mothers. A very large number of women more especially among the poorer classes have not the least idea of the proper management of children and if the natural food—human milk—cannot be supplied the lot of the infant is often hard indeed. The out-patient departments devoted to the diseases of children are crowded with such cases, the unfortunate little patients either being afflicted with gastro-enteritis or practically dying from starvation. The treatment of these conditions is beset with considerable difficulties. The mothers or the custodians are firmly imbued with the idea that "a bottle of medicine" is all powerful and will cure all infantile ailments irrespectively of dietetic irregularities and they resent any attempts at instruction as to how infants should be fed. Some authorities maintain that chilling of the surface may cause simple diarrhœa; infants when first short-coated occasionally suffer in this way. The above conditions are operative throughout the whole 12 months but the rapid alterations of temperature that so often occur during the late summer in this country are particularly likely to be followed by an extensive outbreak of diarrhœa amongst the children. Dr. EUSTACE SMITH[2] points out that rickety subjects, probably on account of the profuse perspiration to which they are liable are especially prone to suffer from these atmospheric changes and in infants who are teething the process of dentition, as it excites a certain amount of fever, is often accompanied by a mild relaxation of the bowels. The most severe forms of diarrhœa occur during the summer heat, and some interesting observations have been made to explain this seasonal increase of intestinal irritation. The late Dr. HILARY TOMKINS, Dr. J. PRIESTLEY, and others have demonstrated that the diarrhœa death rate follows a rise in the temperature of the earth—the hotter the summer the further will the heat penetrate into the earth. Consequently, at the end of a hot season, such as has been experienced this year, the mortality from infant diarrhœa is found to be high. Further, this disease is rarely seen out of large towns and many observers regard the affection as a contagious zymotic disease. The presence of a pathogenic organism has been frequently sought for and many forms of microbes have been isolated from the stools. Dr. V. C. VAUGHAN obtained from certain micro-organisms albuminous products which when injected under the skin of kittens caused vomiting and purging and if in sufficient quantity collapse and death. As yet, however, no special organism has been found to be invariably associated with the attacks. In all probability milk is the chief medium by which the germs find their way into the alimentary canal. Inflammatory conditions in the cow probably have a pernicious effect on the milk. During certain epidemics of acute gastro-enteritis the streptococcus longus was found in the milk supplied by cows that were suffering from mastitis. Dr. HOLST who investigated these cases states that these cocci when injected into mice and rabbits, set up diarrhœa and when swallowed by himself caused colic and vomiting. Dr. EUSTACE SMITH observes that in the most virulent cases of infantile diarrhœa the whole course of the illness points to a septic origin, especially as the patient often dies, not merely exhausted by the drain from the bowels, but in a state of nervous collapse which may continue for many days after the character and the number of the stools have ceased to be a cause for anxiety. Another significant fact is that this septic variety of diarrhœa attacks strong subjects as well as weakly ones; indeed a condition of sturdy health, although it may influence the issue of the illness, seems to afford little protection, if any, against its onset. On the other hand, a delicate child is more prone than a strong one to suffer from the non-septic forms of purging.

The above considerations suggest certain measures which might be adopted to prevent the very extensive occurrence of infantile diarrhœa. In the first place, careful supervision of dairies and cowsheds during the summer months should be insisted on and any case of mastitis carefully treated. It would be desirable that further investigations should be made in order to ascertain the infective nature of the milk, both boiled and unboiled, obtained from cows suffering from this affection. Liverpool has set an excellent example in establishing depôts from which parents can obtain sterilised milk and this plan has proved successful in diminishing the death rate from diarrhœa. The most important matter, however, is to try to adopt some means by which instructions could be given to women as to the proper management of children. Unfortunately, there appears to exist much prejudice against tuition on the part of those immediately concerned. As our Liverpool correspondent points out, there are thousands of mothers who cannot suckle their children but there are also a very large number who refuse to give their infants sterilised milk. If classes could be formed at which instruction could be given in those matters, not only to the married women amongst the poorer classes but also to district nurses and visitors, who might in their turn convey the necessary instructions to the mothers in their own homes, doubtless beneficial results would follow. As is well known, milk is liable to decomposition in hot weather and unless scrupulous cleanliness is observed in regard to the vessels in which the milk is kept, particularly the feeding bottles, evil results will surely follow. We have frequently pointed out the duties which devolve upon medical practitioners in educating patients suffering from pulmonary tuberculosis as to the prophylactic measures which they should adopt in order to prevent themselves becoming a danger to others. So in the matter of the artificial feeding of children a little instruction to the mothers and supervision of the surroundings would doubtless do much in the prevention of one of the most fatal of infantile diseases.

◆

School Sanitation at Blackburn.

THE Health and Education Committees of the County Borough of Blackburn have given very remarkable evidence of the excellent spirit in which they have entered upon the important duties imposed upon them by the Education Act and have set an example which will, we hope, be widely followed in other localities. They have instructed their medical officer, Dr. ALFRED GREENWOOD, to make a complete investigation into the sanitary conditions of the 52 public elementary schools under their jurisdiction and his report, an octavo volume of over 400 pages, with detailed plans of the schools and numerous tables, has been published under their direction. Dr. GREENWOOD, it is hardly necessary to say, has acquitted himself in the most admirable manner and has produced a report which may well serve as a model for any who are called upon to undertake similar duties. He first summarises the rules for planning elementary schools which have been issued by the Board of Education, comparing them in some respects, and not always to their advantage, with those which are in operation in America; and after a general discussion of the questions of superficial and cubic space, of roofs, entrances, and staircases, of cloak rooms and lavatories, of lighting, of ventilation, of warming, of sanitary arrangements, of desks and seats, of water-supply, of sites and playgrounds, and of infants' schools, he gives a copy of the form which he employed for the purpose of systematically recording the results of his inspections—a form in which no single point appears to have been overlooked. A second chapter gives the detailed results of this inspection for every school, with a plan and measurements of every room in each, and with definite recommendations for the correction of every defect that was discovered. The third chapter contains the results of a chemical examination of the air of schools for carbon dioxide; the fourth, the results of a bacteriological examination; and the fifth is devoted to general recommendations in addition to the specific ones made for each school. The total result is that a comparison of the volume with the state of the schools at any future time will afford conclusive evidence of the extent to which the committees concerned have set themselves to remedy faults which have been officially brought under their notice and of which no one can now profess to be ignorant. Out of the mouth of their own officer the Blackburn authorities will in the future be either justified or condemned, and the publication of his report may be taken as an eminently hopeful indication of their intentions. In the meanwhile it is satisfactory to note that the quality of schoolroom air, as tested by the quantity of carbon dioxide, has definitely improved in Blackburn since the date of an examination made seven years ago, and Dr. GREENWOOD attributes the improvement to a better recognition of the importance of ventilation by the teachers.

The chapter of the report relating to the bacteriology of schoolroom air can only be described as somewhat meagre, or at least as descriptive of researches which might have been extended with advantage. They consisted only of the exposure in the rooms for short periods of gelatin or agar plates and of the subsequent counting of the colonies which grew upon them, without any attempt to determine the precise character of the bacteria concerned or the sources from which they were derived. Dr. GREENWOOD makes no reference to the work of FLUGGE on the identification of salivary bacteria suspended in the atmosphere—work which, if we are correctly informed, has recently been considerably extended by inquirers in this country, with especial reference to the distribution of such bacteria by speaking laughing, sneezing, coughing, or even by ordinary expiration. Many of our readers will remember a picture by MULREADY, now in the South Kensington Gallery, entitled "Choosing the Wedding Dress." It hangs at about sight level, and after it had been exhibited for two or three years the attention of the keeper of the gallery was directed to a marked change in the character of its surface—a change which was traced to the projection against it of an infinite number of droplets of saliva from visitors who had stopped in front of it and had laughed as they looked. The resulting film of dried saliva was cleaned away and the picture was then placed under glass for its protection. This coarse experiment, as well as the more delicate ones to which we have referred, must be held to show the importance of the bacteriological study of schoolroom air in relation to the spread of many infectious diseases, and not merely, as Dr. GREENWOOD appears to have regarded it, as a measure of atmospheric impurity. Even in this form, as it does not appear to have been employed previously at Blackburn, there are no data for a comparison between the present and earlier times; but it may be assumed that observations of a similar kind will be continued and extended, and that important results are likely to be obtained from them. It would, of course, be of special importance to examine suspended salivary bacteria at periods when diphtheria or other diseases affecting mucous membranes were prevalent in the district, and it is quite possible that timely warnings of danger might in this way be obtained.

We cannot leave the subject of school sanitation without calling attention to an extremely interesting pamphlet, reprinted from the *Medical Chronicle* for June, in which Dr. R. T. WILLIAMSON of Manchester, the delegate from the Victoria University of Manchester and the Manchester and Salford Sanitary Association to the first International Congress of School Hygiene, held in April at Nuremberg, gives an account of the proceedings in which he took part. It has long been evident to ophthalmic surgeons that a large proportion of the books used in schools are printed in such small and crowded type as to be exceedingly objectionable; and Dr. WILLIAMSON quotes from COHN a simple test of the fitness of a printed page for school use which ought to be universally known and employed. It consists of an ordinary card, say a visiting card, in the centre of which a square hole is cut, each side of which measures exactly one centimetre. The card with the centimetre square hole is placed upon the page to be tested, the lower margin of the hole being immediately above a line of print. If the type be satisfactory only two lines of print can be seen within the square, and, according to COHN, all books should be condemned in which this condition is not fulfilled. An account is given of a very simple and ingenious contrivance, also devised by COHN, for testing the illumination of every part of a room, the requirement to be fulfilled being that at least 20 small figures should be read in 30 seconds at a distance of 40 centimetres from the eyes. Dr. GREENWOOD and other medical officers of health who, like him, feel the importance of such an extension of their work as may bring the requirements of schools completely within their cognisance and under their control, may render good service by directing the attention of their committees to many matters of this kind, and it may be hoped that when the second International Congress is held in London in 1907 the contributions of Englishmen to its proceedings will be of sufficient number and importance to show that the value of the children of the nation, as part of its capital and as a support when speaking with its enemies in the gate, has not been lost sight of either by the members of the medical profession or by the various and sometimes rather heterogeneous local authorities to whose tender mercies the education of these children has been committed.

Annotations.

"Ne quid nimis."

HEALTH AND EDUCATION.

ONE of the most serious obstacles to the progress of sanitary reform in this, as, indeed, in most other countries, has been, and is, the indifference on the part of the masses to all ordinary considerations of personal hygiene. The public health in the aggregate mainly depends on the hygienic morality of the individual. No legislation can enforce the open window any more than it can stop expectoration in the streets. The only practical measure which holds out any prospect of success of improving the standard of personal hygiene among the people is to educate the rising generation in its elementary principles and in the advantages which are likely to accrue from their observance. That this method of utilising the receptiveness of the child's mind and of reaching the objective by a route apparently so circuitous is founded on sound principles and fruitful in practice is clearly evidenced by the marked improvement in the general appearance of neatness and cleanliness of the children who attend at the public elementary schools. But to engender a proper sense of the advantages of an enlightened domestic and personal hygiene it is not only necessary that the teachers themselves should have an adequate knowledge of the essentials of sanitation and hygiene, but also that the precepts which they teach should be pushed home by example and by a strict observance of their laws in the administration of the schools themselves. In this connexion the report of the committee intrusted by the British Association for the Advancement of Science with the duty of inquiring into the conditions of health essential to the carrying on of the work of instruction in schools has naturally been received with considerable interest. This report, which was recently read at the meeting of the association at Cambridge, embodied, among a number of other important considerations, draft recommendations for a course of study in hygiene to be pursued by those proposing to act as teachers in the public elementary schools. The proposed curriculum, though necessarily incomplete and schematic, cannot be regarded otherwise than as well adapted for fulfilling the purposes for which it is intended—that is to say, of providing a course of instruction in hygiene for teachers which will not only enable them in their turn to instruct their pupils in the ways of personal health but also to conduct the general management of the schools and class rooms with an intelligent appreciation of the aims and objects of hygiene and sanitation.

DIFFICULTIES OF CHLOROFORMISATION.

THE extreme difficulty which often confronts the anæsthetist is well illustrated in the clear notes furnished to us of a death under chloroform. The method which appears to have been carried out carefully is one which must always render irregular doses of chloroform possible. Care, such as was used in the present case, and experience undoubtedly lessen its dangers and many competent authorities rely upon the method and even regard it as one of the best competent hands. The facts of the case are as follows. On August 16th the patient, a male, aged 30 years, an ex-soldier, of somewhat slight physique and pale complexion, was anæsthetised in order to have a necrosed femur operated on. Examination prior to administration of the anæsthetic showed the chest, heart, and lungs to be apparently normal. *Chloroform was given from a drop-bottle on* a flannel mask. The patient passed easily to the second degree of anæsthesia, when he struggled with his arms for a second or two and then went on quietly taking the anæsthetic until the breathing being quiet and regular, the pulse about 90 and of fair quality, the pupils about three and a half millimetres, and colour as at the commencement of anæsthesia, he was wheeled into the theatre from the adjacent room and put on the table. Directly this was done the face became pale, the lips and ears cyanosed, the patient gave about eight or ten gasping inspirations like the inspiration of air-hunger, and respiration ceased. Immediately on the alteration of the colour and respiration the head was lowered and artificial respiration was commenced, and a hypodermic injection of strychnine and an enema of brandy were given. The administration of the chloroform had been stopped whilst the patient was being lifted from the stretcher on to the table. The heart failed when the change of colour took place before the complete cessation of respiration; this observation was made by the surgeon in charge of the case. Artificial respiration was persisted in for three-quarters of an hour but without result. The administration of the anæsthetic had been in progress for seven minutes; the amount of chloroform used was three and a half drachms. No necropsy was made. The salient features about the case, so far as can be judged without having witnessed the phenomena exhibited by the patient, appear to be: slight struggling, such as is common to the second degree of chloroform narcosis and failure of respiration ensuing upon lifting the patient from the wheeled couch on to the operating-table. We may presume that *during this struggling the chloroform mask was removed* from the patient's face. If this were not so an overdose would readily be given and its results might not show themselves can sustain life on the most widely different dietaries and we may take it that for the ordinary man that diet is the best on scientific and utilitarian grounds which affords the necessary proximate principles in the most assimilable form consistent with palatability and cheapness. That in this country this is attained by a mixed diet containing a small amount of animal proteid is a matter of general experience.

REVOLVING HOUSES.

ON, no doubt, quite sufficient grounds experts in hygiene are accustomed to lay a good deal of stress on the importance of correctly orientating dwelling houses, so that they may receive the maximum amount of light and of protection from cold winds. It certainly does appear that, in this country at any rate, the more the rooms in which we live are exposed to the rays of the sun the better, for sunlight seems to be at once stimulating to human vitality and destructive to that of many objectionable low forms of life. Experience has taught us to select as far as is practicable a southern aspect for our houses, but even when this is done the fixity of the structure prevents our regulating the supply of sunlight to different rooms according to our varied tastes. Two French gentlemen—Dr. Pellegrin and M. E. Petit, an architect of Paris—propose to change all this. They have designed a method of erecting houses on rotating platforms, so that the building can be made to face in any required direction at any time. The platform is supported on two concentric walls, the inner chamber so made containing a stairway, and the axis of rotation is occupied by a shaft through which pass the supply and waste pipes of the house. A gas or petrol engine is employed to move the platform—and if necessary it can be used to drive clockwork which will enable the house front to follow the sun during the day. There are obvious difficulties in the way of the general adoption of schemes of this kind but the idea is one worthy of the attention of British architects.

NEPHRITIS DUE TO BORAX.

THE extensive use of boric acid and borax as food preservatives has led to repeated controversies as to whether they are injurious to the consumer. The correspondence which is now appearing in our columns demonstrates the various opinions that are held and the difficulties that may arise in sifting evidence on the subject. The question is not easy to settle because a preservative which would cause obvious injury after being taken in food for a short time could not come into general use. Occasional ill effects, such as have been ascribed to boric acid, have been attributed to idiosyncrasy or regarded as a mere coincidence and due to other causes. The only other source of evidence is experiments on animals. It has been stated by Dr. Féré and others that the medicinal use of borax is attended by the risk of producing or aggravating renal disease but this has been denied by Liebreich. In the *American Journal of the Medical Sciences* for September Dr. Charles Harrington has described some important feeding experiments which support Dr. Féré's conclusion. 12 healthy cats were fed on the same food. One was given no preservative, six were given borax, and the remaining five were given a preservative which proved to be innocuous. The quantities of borax given to the cats were as follows: No. 1, 72·5 grammes in 133 days (average daily dose 0·54 gramme); No. 2, 112 grammes in 133 days (average daily dose 0·84 gramme); No. 3, 28 grammes in 42 days (average daily dose 0·66 gramme); No. 4, 108 grammes in 133 days (average daily dose 0·81 gramme); No. 5, 106·5 grammes in 133 days (average daily dose 0·8 gramme); and No. 6, 48 grammes in 56 days (average daily dose 0·85 gramme). Of the 12 cats three became ill and these had all taken borax. No. 4 soon sickened and died at the end of the sixth week. The other two were ill occasionally but during the last weeks of the experiments appeared to be normally active. At the expiration of the periods given above the remaining 11 cats were killed. The necropsies of those which had not taken borax showed no lesions. In the bodies of those which had taken it, with the exception of No. 2, nephritis was found. Stained sections of the kidneys showed lesions of the same character differing in intensity. The epithelium of the tubes, particularly of the convoluted tubes, was degenerated. The normal fat vacuolation was greatly increased and the cells were swollen and in places disintegrated with fragmentation of nuclei. In the lumen of many of the collecting tubules were granular masses representing cell fragments. Some tubules were almost completely stripped of epithelium. In one kidney the change was confined to intense degeneration with hyaline casts in the small tubes. In the others the degeneration was not so intense but was accompanied by foci of cellular infiltration, chiefly marked at the cortex. Where the infiltration was most intense the tubules were entirely destroyed. The lesions were analogous to those of subacute and chronic nephritis in man but did not correspond to any definite type. It may be objected that the daily dose of borax in proportion to weight was much greater than a person would receive in food. But this is not so and, moreover, it has been asserted that borax is quite innocuous even in large doses. A person may easily take in the course of the day in preservatives used in food large quantities of borax without knowing it. The following list showing the quantities of borax used as a preservative shows the possibilities: milk, 2 grammes per quart; butter, 2 grammes per pound; cream, 1 gramme per pint; oysters, 4·5 grammes per pint; corned beef, 18 grammes per pound; ham, 18 grammes per pound; and sausages, 4 grammes per pound. Thus in the day a person might easily take in such food as much as 14 grammes of borax.

THE WORK OF THE RED CROSS SOCIETY.

A SOMEWHAT lengthy but none the less interesting review, by Dr. E. Laval, of the work of the Red Cross Society appears in the numbers of the *Revue Scientifique* dated August 27th and Sept. 3rd, under the title of "La Croix Rouge en France." The purpose of the articles is to urge upon the people of France the need for extending the operations of those associations which represent the society so that the cause of humanity may be served as well in times of peace as during war. As showing how large is the field open to the efforts of the beneficent a comparison is instituted with other European countries from which we learn how varied are the activities of the different bodies which originated as a result of the Geneva Convention of 1864 and the primary object of which was the relief of the distresses incidental to resort to arms. In Germany the Red Cross Society assists in the management of the "Unfall-Stationen," or stations for the care of the victims of accidents, and at these stations the members of the Patriotic Union of Women, a branch of the Red Cross Society, receive training. Against tuberculosis the society has fought by: (1) promoting the building of sanatoriums; (2) looking after those dependent on the invalid during his stay in the sanatorium; (3) helping those discharged from sanatoriums to obtain employment; and (4) seeking out early cases of pulmonary tuberculosis and urging upon them the necessity of treatment while there is a good prospect of recovery. Further, the German branch of the society, carrying out the idea of our fresh-air funds and similar institutions, provides in the woods near Berlin rest-houses, or "Erholungsstatten," where sick persons, to whom special facilities are given for the journey, may spend the day under the supervision of some competent person. In Austria the society has done its best to check the spread of epidemic disease, as, for instance, by the provision in 1899 at Landskron (Prague) and Jadendorf (in Silesia) of accommodation and medical care for those suffering from typhus fever. The Spanish branch devotes itself to State hygiene—e.g., combating approaching epidemics by encouraging disinfection—and it has also on occasion brought succour to sufferers from floods and fires. One of the features of the work of the society in Switzerland is the establishment of an employment bureau for nurses, while in Italy the society has done much to check the mortality from malaria by founding in 1901 six ambulance corps to transfer cases from the malarial regions to the hospitals in Rome. Japan in 1883 took up the matter with characteristic thoroughness and its Red Cross has now 600,000 followers who come to the help of those affected by all public calamities whether earthquakes, floods, shipwrecks, railway accidents, or epidemic diseases. France with its colonies has a population of about 75,000,000 but only 120,000 persons among these display a practical interest in the humanitarian schemes of the three bodies which, without really constituting branches of the Red Cross Society, carry on its work. These bodies are (1) the Société de Secours aux Blessés des Armées, founded about 1864, the utility of which has been greatly impaired by internal dissensions; (2) the Association des Dames Françaises, which was established in 1879 and from which split off in 1881 (3) the Union des Femmes de France. Dr. Laval's paper is an earnest appeal to these different agencies to sink their jealousies for the common good and to combine in the construction of a charitable organisation which shall remove the reproach of selfish indifference to the woes of their fellows from the wealthier classes in France.

THE APPRECIATION OF NOTHING

IN the Middle Ages philosophers were acutely divided on the question as to whether things were really things or only names—that is to say, whether they were something or nothing—and the late Lord Iddesleigh when Sir Stafford Northcote once held a village audience in wrapt attention while he delivered a lecture "On Nothing." The conception of nothing is as difficult for the finite mind as is that of infinite space and perhaps of all the arts the one best adapted to express nothing is the highest of the fine arts—namely, music. During the present season of concerts at the Queen's Hall Mr. Wood and his magnificent band have given voice to the thoughts of three composers who in two cases purposely, and in one case apparently, have striven to represent nothing. The apparent case was a composition by M. Claude Debussy, a leader in the most modern French school of composition. His "Après midi d'un Faune" goes as near to the audible expression of a day-dream as anything audible can, although what a faun, which is not a gazelle, as the critic of a contemporary believes, does think about we should say that no one knows. Of the other two pieces that by Sir Edward Elgar is founded upon a passage of Lamb which occurs in the essay, "Dream Children," and which runs: "We are not of Alice, nor of thee, nor are we children at all. . . . We are nothing; less than nothing, and dreams. We are only what might have been." The third piece is the amazing scherzo movement from the Fourth Symphony by Tchaikowski of which the composer gives his own interpretation thus: "In the third movement no definite feelings find expression. These are but capricious arabesques. One thinks of nothing. . . . These are the incoherent pictures which float before the fancy divorced from reality." Anyone who hears this movement will recognise with what truth the composer has succeeded in representing nothing, especially in that part of the movement which is allotted to the pizzicato strings. Music, to those who know how to hear, brings home the higher activities of mentality better than any other medium and the psychologist and the thinker may find that abstractions become clear when presented to their minds by the joint art of composers, instrumentalists, and a conductor of such quality as are to be found at Queen's Hall.

THE NEW DIRECTOR-GENERAL OF THE MEDICAL DEPARTMENT OF THE NAVY.

THE Admiralty has issued the following notice:—"Inspector General of Hospitals and Fleets Herbert MacKay Ellis has been appointed Director General of the Medical Department of the Navy in the place of Sir Henry F. Norbury, K.C.B., R.N., whose term of office has expired. To date the 12th September, 1904." The new Director-General served with the battalion of Royal Marine Artillery throughout the campaign in Egypt in 1882, being present at the two engagements at Kassassin and at the battle of Tel el-Kebir. He was mentioned in despatches, promoted to the rank of staff surgeon, and was awarded the medal with Tel el-Kebir clasp and the Khedive's bronze star. He was fleet surgeon of the *Victoria* when she was rammed by the *Camperdown* off Tripoli in June, 1893. His last appointment was that of inspector general in charge of Haslar Hospital. We consider that the Royal Navy Medical Service is to be much congratulated upon this new appointment.

RECOVERY FROM MALIGNANT ENDOCARDITIS.

THE following case, reported in the *Boston Medical and Surgical Journal* of July 28th by Dr. C. F. Withington, is of interest both because of the rarity of gonorrhœal endocarditis and because it is an example of recovery from malignant endocarditis—the possibility of which has been questioned. A man, aged 26 years, was admitted to hospital on April 19th, 1904. A first attack of gonorrhœa began on March 8th. Two weeks later he had measles. During convalescence from the latter disease he was seized with severe pain in the region of the heart and dyspnœa which lasted for four hours. Chills, irregular fever, sweating, and cough followed and persisted up to the time of admission. Four days before admission he had pain in the left leg which rapidly swelled and turned purple. On admission he looked very ill. The temperature ranged from 102° to 103° F. and the pulse from 160 to 170 and there was orthopnœa. Cardiac dulness extended three centimetres to the right and 16 centimetres to the left of the middle line. A presystolic thrill was felt below the nipple but no murmur was heard at the apex. A short systolic murmur was heard in the left fourth intercostal space. There was "gallop rhythm." At the bases of the lungs were limited areas of consolidation. There was marked phlebitis of the left leg throughout. The left calf measured three inches more than its fellow and the thigh was only a little less swollen. There was marked tenderness over the popliteal and femoral veins. A leucocytosis of 16,200 was present. During the next few days the action of the heart grew less tumultuous, the murmur became more distinct, and the pulmonary second sound increased. The temperature ranged between 101° and 103°. Blood taken from the bend of the elbow on April 25th yielded a culture of the gonococcus, confirming the view that the endocarditis was gonorrhœal. The temperature became normal on the 28th and two days later the phlebitis was less distinct. On May 8th the murmur was still present but there were no other cardiac symptoms and the area of cardiac dulness was diminished. Early in June the patient was in fair health the murmur was still heard but the areas of pulmonary consolidation, which were thought to be embolic, were nearly resolved.

THE AMBULANCE IN CIVIL LIFE.

A *brochure* on "Ambulance in Civil Life" is again published as a sixth edition of the address delivered in 1881 by Mr. Reginald Harrison as President of the Liverpool Medical Institution. The present issue, however, contains an account of the efforts that are being made by the Metropolitan Street Ambulance Association to secure for the County and City of London an improved ambulance service. To this end we wish it every success and hope that what was suggested many years back by the Hon. Francis D. Leigh in the *Nineteenth Century* and by Mr. S. Osborn of the St. John Ambulance Brigade will eventually be realised. Without entering into prolonged details of what has been done and what is required great credit should be given to Sir John Furley who was the first to organise any work of this description in the streets of London. The Metropolitan Corps of the St. John Ambulance Brigade with its able body of volunteer workers was started 25 years ago and the present chief surgeon, Mr. S. Osborn, with Mr. J. Brasier and Mr. W. H. Morgan, who then assisted Sir John Furley in his first efforts, still continue to render good service in the streets on all public occasions, and with them must rest the honour of being the first workers in a cause which we should like to see perfected for constant service by incorporation with some such body as the Metropolitan Fire Brigade. Of course this would mean the supplementing of that admirable body of workers by a sufficient number of men, horses, and ambulances to deal efficiently with the task, but this scheme has already been fully considered by the Metropolitan Street Ambulance Association.[1]

ACETONURIA AND DEATH AFTER ANÆSTHESIA.

IN the *Boston Medical and Surgical Journal* of July 7th Dr. E. G. Brackett, Dr. J. S. Stone, and Dr. H. C. Low have reported a series of cases observed at the Children's Hospital, Boston, in which death occurred in peculiar circumstances. On Oct. 6th, 1903, a boy, aged 10 years, suffering from infantile paralysis but otherwise apparently well, was admitted. Four days later he began to vomit persistently light green fluid. The bowels had acted freely and the abdomen was soft and not distended. The pulse became very weak and rose to from 90 to 150 and the temperature rose to 105·8° F. He became unconscious and died 20 hours after the onset of the symptoms. On the same day a girl, aged eight years, was admitted also suffering from infantile paralysis. She seemed delicate but otherwise was sound in health. Several times in the preceding year she had had attacks of persistent vomiting with collapse. Four days after admission three tendon transplantations were done under ether. The operations occupied one and a half hours and were not severe or attended by hæmorrhage. The child took the ether badly and during the operation had a rapid pulse. 12 hours after recovering from the anæsthetic she seemed in fair condition. Then she suddenly began to vomit persistently. The pulse became weak and rose to 190 and the temperature rose to 106°. The vomiting lasted about 30 hours. She gradually sank into a delirious stupor and died 42 hours after operation. Six weeks later, on Nov. 17th, a girl, aged five and a half years, with extensive infantile paralysis had the fascia on the upper and outer part of both thighs divided. She recovered well and was comfortable up to 13 hours after the operation. Then she began to vomit. 24 hours after operation the face became cyanotic, the extremities cold, the pulse weak and rapid, and the expression anxious. She gradually became comatose and died 48 hours after operation. A peculiar sweet odour from the breath led to examination of the urine for acetone and diacetic acid which were found. On Dec. 17th two girls with extensive infantile paralysis, aged six and eight years respectively, were admitted. One began to vomit after six hours and the other after 15 hours. Both became stupid; there was an odour of acetone from the breath and the urine contained acetone and diacetic acid. Both recovered. On Dec. 26th a girl, aged four years, was admitted. For six days she had been vomiting and the bowels had not acted. The odour of acetone in the breath was very strong and acetone was found in the urine. Intestinal obstruction caused by a Meckel's diverticulum was relieved by operation. After recovering from the operation she became unconscious and died at the end of 26 hours. Subsequently a sweet odour from the breath was noticed in a number of patients after operation and acetone was found in the urine. In most of them vomiting occurred and some of them showed marked prostration. Only one case was fatal. In the fatal cases the necropsies showed some fatty degeneration of the liver, kidneys, and muscles. Death after anæsthesia with acetonuria has been previously recognised. In 1894 Becker reported from the Bonn clinic three fatal cases after operation on diabetic subjects whose condition previously had not caused any apprehension. Brewer in the *Annals of Surgery* for October, 1902, reported a fatal case of acetonuria after operation for appendicitis. In THE LANCET of July 4th, 1903, p. 10, Dr. L. G. Guthrie published an article entitled "The Fatal Effects of Chloroform on Children Suffering from a Peculiar Condition of Fatty Liver." The symptoms resembled those of the cases described above. He thought that death was due to auto-intoxication brought about by three factors—the fatty condition of the liver, the shock of the operation, and the chloroform. The phenomena of acid auto-intoxication apart from diabetes has been studied by von Jaksch, Lorenz, Baginsky, and others. Becker found that after anæsthesia in healthy persons a distinct amount of acetone was present in the urine. But in one of the fatal cases now reported and in some of the milder ones the symptoms occurred without operation or anæsthesia. Perhaps the effects on the nervous system of admission to hospital—home-sickness, dread of operation, and so on—may have affected the metabolism and produced acetonuria. In addition to stimulants, bicarbonate of soda was given to combat the acid intoxication and seemed to have a beneficial effect. Very little is known of acid intoxication and the whole subject, as well as its relation to the administration of chloroform, obviously requires further investigation.

THE ACTION OF RADIUM ON FROGS AND MICE.

Dr. E. C. London of St. Petersburg, whose early experiments with radium are well known, has, according to the *Pharmatzevtitcheski Journal*, published a work giving details of his latest investigations, having as their object the elucidation of the action of radium on animal life. One of them was as follows. A solution of radium bromide was placed in a retort connected by tubing with another glass vessel, both of them being stoppered. In the second reservoir he kept live animals, generally frogs or mice, which were preserved from suffocation during the experiments by means of the periodical admission of fresh air. It was found that frogs placed in a vessel with water in which radium emanations were diffused became flabby and dull; in six or seven days their breathing became troubled and their skin showed want of freshness. These symptoms became more and more accentuated up to the thirteenth or fourteenth day, when the animals died. Flakes from their skin floated in the water. On being taken out their skin was found partially to be decomposed and the blood was abnormally dark in colour. Moreover, from the first day of contact with the radium emanations the frogs became radio-active. Mice died sooner than frogs; after being left for four hours in the vessel where radium emanations had accumulated for 48 hours previously they sickened and died on the third day although showing no signs of illness previously. Dr. London supposes that they died from an affection of the air passages induced by the action of the radium.

---

SEEGEN PRIZE

A PRIZE under the above title of 6000 kronen (£240) has been offered by the Vienna Academy of Science for an essay on the following subject: "To settle the question whether or not a portion of the nitrogen of the albumin which has undergone metabolism in the system is excreted in the form of free gaseous nitrogen either by the lungs or through the skin." The essays may be written in the German, French, or English languages and must be sent in to the Chancellor of the University of Vienna before Feb. 1st, 1906.

IDIOPATHIC EPILEPSY IN A CANARY

CASES of idiopathic epilepsy are rare in the lower animals. Nearly all such cases previously reported, especially in the bird, where necropsies have been made have proved to be Jacksonian epilepsy of traumatic origin. In the *Journal of Nervous and Mental Disease* for August a case is reported by Dr. Pierce Clark of New York of idiopathic epilepsy in a canary which presented many features of interest. The bird was a male one year old, from an apparently healthy brood of four. When it came under observation it was the *subject of typical idiopathic attacks of grand mal* with irregular attacks of *petit mal* at intervals of every few days. An attack of *grand mal* was as follows. The bird uttered an epileptic cry and fell backwards from the perch in a stiff general tonic spasm which lasted about 30 seconds. It lay very still on its left side where it had fallen. Then followed a very short clonic spasm during which the head was turned to the left side and the legs were fully extended. After this epileptic convulsion the bird exhibited violent excitement of an automatic (subconscious) character. It flew about the cage and dashed itself against the wires. After a few minutes of this sort of activity it lay quite still in a stage of coma lasting six or seven seconds. "It then began to peep and stagger about the cage, still continuing its automatic purposeless acts, such as treating the seed cup as a water cup and *vice versa* without partaking of the contents of either. After two minutes the attack gradually wore off and the bird acted normally although it appeared somewhat dazed and did not sing for the next few days. Treatment was adopted of giving bromide by adding a 1 per cent. solution of potassium bromide to its drinking water. Much improvement resulted in the next two weeks, the bird again beginning to sing and to act in the normal manner. Symptoms of bromism (apathy and somnolence) appearing, the dose was reduced. During the next four months only weekly attacks of *petit mal* of a very slight character occurred. Unfortunately, owing to accidental omission of the bromide for a fortnight, a violent series of attacks of epilepsy came on with post-convulsive exhaustion paralysis as follows. The bird gave the epileptic cry and fell backwards from the perch as before. Then followed *tonic spasm for 30 seconds with retraction of the legs* and turning of the head to the left. Clonic general spasms followed with extension of the limbs, including the wings, and fine tremors and jerkings of the same. The eyelids were in rapid nictitation and the mandibles were opened and shut rapidly in clonic spasm. The bird then dashed about the cage as previously described, only more furiously; finally it lay exhausted as though dead at the bottom of the cage (stage of coma). The attacks grew worse daily and the bird, soon exhausted by them, was no longer able to mount its perch. The bromide was again given to note the therapeutic effect and improvement followed. For a period of eight days the attacks ceased and the bird gained steadily in strength and was apparently normal once more when one day it was discovered in a peculiar position, standing with its toes outspread and resting partly on its tail. Rapid clonic spasms and a *rhythmical nodding of the head, as well as fibrillary twitchings* of the body generally were noticed. It grew worse and died in a few hours. The necropsy, which was made ten minutes after death, showed an apparently normal brain in every respect, the calvarium being also normal. The epileptic attacks, the post-epileptic exhaustion paralysis, the status epilepticus, and mode of death were in many clinical respects like the same in man.

THE OPERATIVE TREATMENT OF ENTROPION AND TRICHIASIS

THE frequency with which trachoma followed by entropion and trichiasis occurs in Australia has led to numerous operations being devised and practised for the relief of those unfortunate patients who suffer from these troublesome sequelæ of granular lids. The *Ophthalmoscope* for the present month contains an article by Dr. J. W. Barrett and Dr. W. T. Orr, respectively surgeon and assistant surgeon of the Victoria Eye and Ear Hospital in Melbourne, giving an account of a method of operating which they have found to be successful. In the first stage of the operation a long cut is made through the skin of the eyelid down to the tarsus and the skin, subcutaneous tissue, and orbicularis muscle are dissected upwards; gut sutures are then passed through the edge of the skin adjoining the cilia and are secured to the tarsus in its upper portion which effects the eversion of the cilia. The edges of the skin insertion are sutured with horsehair so that the gut sutures are to a great extent buried. If the tarsus is much incurved a V-shaped strip of it may be removed with advantage. *In the second stage an intermarginal* incision is made from the puncture to the outer canthus, the incision passing up into the substance of the lid behind the roots of the cilia which are all included in the anterior flap. This incision joins that made in the first stage in many places but bridges may perhaps be left here and there. It permits of a certain amount of sliding up of the skin carrying the cilia on the tarsus. In the third stage the posterior flap *containing the tarsus is sutured to the lower* lid by gut sutures so that not only are the cilia displaced upwards but the tarsus is temporarily displaced downwards for a period of from two to four days and the gut sutures are then cut. The horsehair sutures joining the edges of the skin are removed a little later, whilst the gut sutures uniting the ciliary border to the tarsus are either allowed to stay in altogether or are removed when loose. The results are said to be excellent.

ON THE FATE OF THE HAIRS IN CICATRICES

IT is a familiar fact that in the process of repair of injuries to the skin, whether produced by traumatic, chemical, or thermal agencies, no regeneration of hair occurs if the hair roots have been completely destroyed. The surface epithelium which in the process of repair spreads over the injured surface no longer possesses a capacity for the formation of hair, like that of the epiblast in embryonic life. Other results are obtained, however, when the hair roots remain in their natural relation with the dermis, even though the epidermis has been destroyed. Some interesting observations are recorded by Dr. Fritz Lebram on these results in a paper published in the *Centralblatt für Allgemeine Pathologie und Pathologische Anatomie* of July 30th, p. 569. In the first place, little islands of epithelium may start out from the hair sheath and spread over the granulating surface, assisting in the process of healing as shown by F. Marchand.[1] Again, if the hair papilla be uninjured the natural process of growth will go on in addition and a scar will result containing hairs as in the normal skin. On the other hand, the process of granulation tissue formation, and regeneration of the surface epithelium may occur rapidly so that the hair root becomes completely shut in. Under these conditions it may atrophy or develop into a cyst or may continue to grow without reaching the surface. Dr. Lebram describes and figures an example of this latter condition which was obtained from the scar of an operation wound in a case of carcinoma of the breast. In the section a hair is seen cut across in the depth of the scar six times, its apex growing into the deeper parts and not towards the surface. The hair is surrounded by a number of giant cells, having apparently acted as an irritant to the surrounding tissues.

SANITARY MATTERS IN MANCHESTER.

THE report of the Manchester sanitary committee, with its annual record of work up to the end of April last, shows how much the public health depends on the efficiency of the department. From all quarters 47,200 complaints were received by the committee. It is often said, and with a good deal of truth, that the public is apathetic, but they made 2125 of the complaints, while through the medical officer of health's department 27,104 were made, 95 by the police, and 17,876 by the staff. Inspections of registered lodging-houses, of which there are 896, are frequently made. 3996 visits were paid by day and 591 at night. A large number of these houses are not registered and a special inspector has been appointed to look after them. A careful watch is kept over the milk-supply but there are great difficulties in the efficient carrying out of the precautions against the introduction of disease. The need for redoubled care is shown by the increase in the proportion of the various milks taken at the railway stations proved to be tuberculous. It is encouraging, however, to note "that the death-rate from phthisis is much the lowest on record." With regard to small-pox we seem to be becoming resigned to its existence among us, now increasing and again diminishing, the origin often clear, but in other cases eluding all search. This fatalistic attitude is to be deplored. Dr. J. Niven, of course, approves of vaccination and considers that revaccination at the age of 12 years is the essential object to be attained. "If compulsory revaccination at the age of 12 can be brought into operation all difficulties about small-pox hospitals, vaccination of contacts, isolation of families, and so forth, will dwindle to trifling magnitude." In his address to the Sanitary Inspectors' Association at Southport on Sept. 3rd Mr. F. Vacher, the President, medical officer to the Cheshire county council, urged that conscientious objection to vaccination should not be legally recognised and that revaccination should be compulsory. He would remove the oversight of vaccination from the guardians to the sanitary authority. He would have chicken-pox added to the list of diseases compulsorily notifiable and the control of the movements of the vagrant class given to the local authorities. It is pretty certain, however, that the ancient effigy of "the liberty of the subject" would be brought out again, for our theory seems to be that the ignorance or fanaticism of the few shall always be allowed to inconvenience and to endanger the many.

WE regret to announce the death so soon after his retirement in May, 1901, of Surgeon-General James Jameson, C.B., who died at his residence in Eltham, Kent, on Tuesday last, aged 67 years. He was appointed Director-General of the Army Medical Service in 1896 and his retirement was announced in THE LANCET of June 8th, 1901. In a future issue we hope to give an extended account of his career.

THE first congress of the Société Internationale de Chirurgie will be held in Brussels in September, 1905, under the presidency of Professor T. Kocher of Berne. All communications regarding the congress should be addressed until further notice to Dr. C. Willems, delegate for Belgium, 6, Place St. Michel, Ghent.

WE regret to announce the death of Dr. William Lee Dickinson which took place quite suddenly on Sept. 6th at Tintagel, Cornwall. We shall publish an obituary notice in a future issue.

THE EVOLUTION OF MAN'S DIET.

BY HARRY CAMPBELL, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE NORTH WEST LONDON HOSPITAL AND TO THE HOSPITAL FOR NERVOUS DISEASES, WELBECK STREET.

II.[1]

FOOD AVAILABLE FOR THE EVOLVING MAN.

I PROPOSE now to consider the various diet epochs but before doing so it will be well to take a brief survey of the kind of food, animal as well as vegetable, which was available for the evolving man before he had learnt to increase his food-supply by artificial means—i.e., by cultivating plants and breeding animals.

Vegetable Food.

Seeds.—Seeds constituted the most important sources of the vegetable food of man. Containing as they do an embryo plant, together with a supply of nutriment for it, these are of all vegetable foods the most nourishing, inasmuch as besides starch and fat they are provided with a large proportion of the precious proteid which is absolutely necessary for the upbuilding of animal protoplasm. Some, like the grass seeds, are very small and require to be collected in large quantities before they afford an appreciable amount of nutriment, while others, such as acorns, chestnuts, and the seeds of many pines, palms, and leguminous plants, may individually yield a goodly store.

Fruits.—When, as in the case of the sloe, wild apple, and various species of "berries," seeds are enveloped in a brightly coloured and often luscious envelope which subserves the purpose of their distribution by attracting birds, they and their envelopes constitute "fruits." It should be noted, however, that these fleshy envelopes are in the case of all wild fruits, of comparatively little energy value, consisting as they do in the ripe state mainly of a watery solution of sugars and salts; and as the seeds of fruits are specially constructed to resist digestion so as to pass whole through the alimentary canal, being, in fact, quite undigestible unless laboriously masticated, it is obvious that wild fruits do not afford much nutriment. If, however, they are ground or otherwise specially treated the seeds of some fruits—e.g., of the wild water-melon—may be rendered highly nutritious.

A secondary source of the primitive food-supply lay in fleshy roots and green vegetables.

The fleshy roots.—The term "fleshy root" may conveniently be made to include any underground part of a plant (e.g., tuber, rhizome, tap-root) serving as a store-house of nourishment. Such "roots" are of food value chiefly on account of their richness in starch; they contain but a small quantity of proteid and thus can only serve—and this is true even of the cultivated varieties—as accessories to the more nitrogenous foods

---

[1] Deutsche Chirurgie, Lieferung 16, S. 167.

[1] No. I. was published in THE LANCET of Sept. 10th, p. 781.

Green vegetables —Under this term we include the leaves and young shoots of plants, they afford very little nourishment and are chiefly eaten for the watery and saline constituents they contain

Besides all these—seeds, fruits, roots, and green vegetables—among the miscellaneous vegetable substances available as food for the evolving man were *mushrooms*, *seaweed*, the *bark* of certain trees, and *gum*

Contrasting the uncultivated vegetable foods with the corresponding cultivated varieties we find that the former differ from the latter chiefly in containing a larger proportion and denser kind of cellulose, and in being less palatable owing to the presence of bitter and acrid principles, the chief objects aimed at in the cultivation of vegetable foods having been to diminish the cellulose and the disagreeable ingredients and to increase the proportion of starch, sugar, proteids, and fats Other things being equal those vegetable foods which contain the least amount of cellulose and the least dense varieties of it, and the smallest amount of bitter or acrid constituents, are the most nutritive and palatable and therefore the most eagerly sought after This is an important principle as it explains how the evolving man gradually came to leave certain vegetable foods out of his dietary

Another point regarding uncultivated vegetable foods on which it is necessary to insist is that they are by themselves totally inadequate to supply man's nutritive needs Even our anthropoid and post anthropoid or homo simian ancestors could not subsist entirely on the vegetable food which nature provided for them One is apt to picture early man as surrounded by luscious fruits and sweet tasting seeds in profusion, as living [illegible] , where a sufficiency of [illegible] e mere trouble of gatherin [illegible] as is sufficiently proved by the fact that even now in spite of their elaborate methods of preparing and thus increasing the nutritive value of their vegetable food, no existing race of men is capable of subsisting upon the products of the uncultivated vegetable kingdom alone The popular belief to the contrary is perhaps in some measure due to the mistaken notion that fruits like the fig, date, and banana grow wild in abundance and constitute even in their wild state highly nutritious foods, whereas, as a matter of fact, they are, as supplied to our markets, the finished products of a cultivation the origin of which is lost in an unfathomable past, while in the wild state they are scarcely recognisable and practically inedible The sugar cane and cocoa nut have similarly been brought to their present state of perfection by centuries of careful cultivation, wild, they furnish but a meagre supply of nutriment

Animal Food

As for the animal food of evolving man it may safely be said that animal food in any or every form was acceptable to him and his homo simian ancestors prior to the cibicultural period Some kinds would naturally be preferred before others, but there can be no doubt that, at any rate in times of dearth, all kinds were greedily devoured, from fish, birds, and birds eggs, and every species of mammal, down to grubs, worms snails, insects, caterpillars, frogs, lizards, snakes and shellfish

Nor among his available foods must we forget to include *honey*, which has afforded a valuable source of nutriment from anthropoid times

THE DIET EPOCHS

In considering the changes which this primitive diet has undergone we shall find it convenient to divide man's dietetic career into epochs and periods The following are those which I propose[2] —

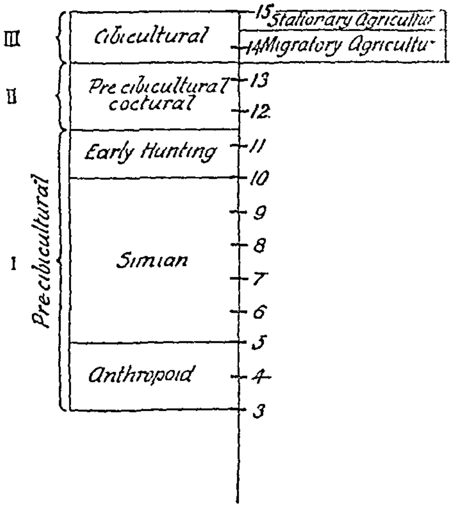
I *The pre coctural epoch* —From the anthropoid stage to the discovery of cookery (3rd 11 5th grade)
- The anthropoid period (3rd–5th grade)
- The homo-simian period (5th 10th grade)
- The early hunting period (10th–11 5th grade),

I [illegible] *epoch* —From the discovery of [illegible] griculture and the breeding of [illegible]

III *The cibicultural* [illegible] age of pap [illegible] grade)

The first, or pre coctural epoch, extends from anthropoid times to the definite establishment of cookery, which I place at the 11 5th grade of evolution (see Fig 3) This epoch

FIG 3



may be conveniently subdivided into three sub-epochs or periods (*a*) The anthropoid period (corresponding to 3rd 5th grade of evolution), (*b*) the homo-simian or, more briefly, the 'simian' period (corresponding to the 5th–10th grade), extending from the anthropoid stage until the time when artificial methods were first employed in hunting and fishing—when, i e , we may suppose racial manhood to have been attained , and (*c*) the early, or pre coctural, hunting period (corresponding to the 10th–11 5th grade), which embraces the period of hunting and fishing before man had begun to cook his food habitually

The second, or coct [illegible] xtends from the commencement [illegible] ce till man began to increase [illegible] plants and breeding animals, and corresponds I suggest, to the 11 5th–13 5th grade of evolution All existing pre-agriculturists are in this diet epoch

The third or cibicultural, epoch, which includes the present time dates from the time man began to cultivate plants and breed animals for food which I assume to have been at the 13 5th grade of evolution So far as agriculture is concerned this period admits of subdivision into (*a*) the period of migratory agriculture and (*b*) the period of stationary agriculture, which may be further divided into an early and a late period, the latter being characterised by the fact that most of the farinaceous food is consumed in a soft, pappy state, for which reason it may not inappropriately be called the "age of pap "

It may, perhaps, appear more accurate to speak of diet *stages* rather than *epochs*, inasmuch as the various peoples of the world have not advanced at equal rates in regard to their diet any more than they have in other respects There has, i e , been a considerable overlapping of the [illegible] [illegible] *wever, we agree to take as the beginning of* [illegible] time at which the dietetic customs characteristic of it first began the term "diet epoch" will have a definite chronological meaning.

It is, of course, impossible to state with any degree of exactness the dates of these various diet epochs and periods and the evolution grades to which they severally correspond, to say, e.g., how many years ago the hunting stage began and what evolution grade had then been reached. I have had to surmise much and doubtless many of my surmises are wide of the mark—thus it is not unlikely that the coctural epoch started before the 11·5th grade—but they may help to give clearness and definition to the otherwise blurred picture of man's dietetic evolution and their conjectural character may perhaps serve to stimulate inquiry.

---

[2] A word as to nomenclature Nothing better shows the neglect hitherto of our present line of inquiry than th [illegible] ready made [illegible] "cooking" [illegible] is employe [illegible] denote both [illegible] derive coctu [illegible] *cibi* in cibic[illegible] formed by taking the genitive of cibus on the same principle as *pisc* and *horti* in piscicultural and horticultural, the *s* of piscis in the former case being omitted for euphony

Taking, now, a general survey it will be seen that the dietetic career of the evolving man from homo-simian times onwards has been characterised by three great advances, with each of which his supply of food has been greatly augmented. (Fig. 4.) The first advance was made when the genuine hunting and fishing stage was entered upon, when man began, i.e., to employ artificial aids in capturing his animal food, and thus came greatly to increase its supply and to be correspondingly less dependent upon vegetable food: until he had invented these he must have been unable, except by lucky chance, to procure any of the larger game and only a very limited quantity of fish. The second advance came when he began to subject his vegetable food to artificial preparation, such as sun-drying, grinding, maceration, burying, and, above all, cookery; this led to a considerable increase in his supply of vegetable food and opened the way to agriculture. The third great advance—preceded by the minor one which was made when he learnt to store his food, especially vegetable food, against seasons of dearth—consisted in the cultivation of plants and the breeding of animals for food; once he had fairly reached this step man in one bound increased his food-supply a thousandfold and was enabled to multiply and progress in a manner which had otherwise been quite impossible.

First great advance.

We will now briefly consider each diet epoch in its leading features, leaving their more complete consideration to future sections.

The anthropoid period.—During this period (3rd to 5th grade) our precursors resembled the present-day anthropoids and probably subsisted on much the same kind of diet as do the latter—i.e., on seeds and fruits, leaves and young shoots, and possibly also roots; and on such animal food as insects, grubs, caterpillars, frogs, lizards, snakes, birds, birds' eggs, and the smaller mammals; honey and gum were probably also consumed. Much of the vegetable food of this period was, by reason of the density and abundance of its cellulose constituents and its admixture with acrid and bitter principles, of a kind quite unsuitable to the needs of the evolving man in his coming phases.

The homo-simian period.—The next long period (5th to 10th grade) saw the simian pre-human struggle upwards from ape to man. He gradually spread over the Indo-African continent, leading, we may conjecture, a comparatively stationary, non-nomadic life, and subsisting chiefly upon raw vegetable food. As his intelligence increased, however, and with it the means of procuring animal food, he became less and less a vegetable feeder and more and more carnivorous, though he was not yet able to procure any but the smaller animals. But with this increase in the amount of animal food consumed he naturally came gradually to abandon and to lose the power of digesting the most indigestible and least palatable forms of vegetable food.

The pre-coctural hunting and fishing period.—This period (10th–11·5th grade) began when the evolving being first learnt to hunt and to fish in real earnest. This he could not do without the help of special weapons and devices: without weapons, traps, or dogs, how was it possible for him to destroy the larger game? He could not, like the carnivora, overcome his prey by sheer agility and strength; with man success in the hunt depends essentially upon intelligence, upon an intimate knowledge of the habits of his prey, and cunning in devising means of trapping, spearing, shooting, or otherwise overcoming it. How, again, without special devices, was it possible for him to secure any but small quantities of fish? While, therefore, there can be no doubt that the diet during the homo-simian period became increasingly animalised, it was not till the hunting and fishing period was fairly reached that the evolving being whom we may now suppose to have attained to the dignity of manhood—the invention of hunting implements surely constitutes a title to this distinction—became actually more carnivorous than vegetarian, and this in the proportion, I should judge, of about three to one. The effect of this large accession of animal food was to lead to a further abandonment of the least suitable kinds of vegetable food, with a corresponding loss in the power to digest them in the raw state. Another effect was that it enabled man to spread into regions which without hunting would not have provided him with sufficient food: we may, in fact, date the spread of man far and wide over the earth from the beginning of the hunting period, though it is quite possible that the general dispersal did not take place until man had learnt to prepare his vegetable food artificially and in this way greatly to increase its supply.

It should be observed in regard to these three pre-coctural periods—the anthropoid, homo-simian, and early hunting—that all the vegetable foods (save the luscious fruits which contain their saccharides in a soluble form) need very efficient mastication in order to break up their undigestible[3] cellulose framework and thus to liberate the contained starch, proteid, and fat. It is therefore evident that throughout these periods the masticatory apparatus of our early progenitors must have been put to ample work. The effect on the starchy portion of food of thorough mastication is worthy of note: it leads to its very thorough insalivation; and inasmuch as the intake of starch in those far-off times was comparatively limited this substance was for the most part digested into dextrines and maltose within the mouth, but little passing into the stomach as crude starch. It will thus be seen that until the discovery of cookery the stomach of the evolving man had very slight acquaintance with undigested starch, saccharide material entering it for the most part in the soluble form, either as grape sugar and fruit sugar, together with a small quantity of cane sugar (as in honey and luscious fruits) or as the products of salivary digestion—i.e., as dextrines and maltose.

The pre-agricultural coctural period (the 11·5th–13th grade).—It is very probable that food was cooked in a desultory way long before this, for there is evidence of fire having been employed artificially in the miocene period.

We are happily able to give an accurate and not merely conjectural account of the dietetic features of this period, since certain peoples are living in it at the present day. I shall in due course give reasons for concluding that man first applied cookery to vegetable rather than animal food; in any case the importance of the discovery of cookery relates almost entirely to its effect on vegetable food. It does not seem improbable that before man learned to cook his vegetable food as a matter of routine he had already begun to prepare it *in other ways, as* by sun-drying, grinding, and burying, by which means its digestibility may in many cases be increased, and by maceration whereby poisonous and acrid ingredients may be got rid of. When he learnt to prepare his vegetable food in these various ways, but esp[illegible] to cook it systematically, h[illegible] for there are many highly [illegible] *which in the unprepared stat*[illegible] amount of dense cellulose they contain or their admixture with obnoxious principles, are of little or no value to him as food, but which by cooking and other means can be converted into valuable nutriment. Hence, with the advance in the art of cookery—and it is suprising to what refinement it had attained in the latter part of this period—the supply of vegetable food steadily increased, and the hunter was to some extent relieved from the chase and more free to devote himself to other pursuits. This increase continued throughout the period under consideration until vegetable food came to constitute one half, or more, of the total dietary.

---

[3] The term "undigestible" is used as distinct from "indigestible."

The chief effect of cooking on vegetable food being the breaking up of its cellulose frame-work and the liberation of the contained nutritive ingredients, cooking greatly aids the digestibility of all such vegetable substances as contain abundance of cellulose and at the same time it relieves the organs of mastication of much of their work; hence when man began to cook his vegetable foods he subjected them to *less mastication than heretofore*, with the consequence that the starchy ingredients were so much the less insalivated, and inasmuch as with the advent of the coctural period more starch was consumed than previously, it is clear that more of it now entered the stomach than had hitherto been the case.

The abandoning of, and the corresponding loss of power to digest in the raw state, the less digestible and palatable kinds of vegetable food which characterised the homosimian and early hunting periods went on with accelerated rate after man had once begun to subject his food to artificial preparation, until he came to depend less and less upon raw vegetable food and finally limited himself to the very easily digestible kinds.

A still more important effect of cookery was that it led the way to the next great dietetic advance—i.e., the artificial production of food by the cultivation of plants and the breeding of animals, without which a high degree of civilisation would scarcely have been possible. It is, no doubt, conceivable that man might have come to breed animals for food without having first discovered cookery, though that he would have done so to any great extent seems unlikely; but that agriculture would not have made great headway without cookery is certain, since much the most important objects of agriculture—i.e., the cereals and pulses, *as well as most roots*—need cooking. *Most cultivated fruits*, and some of them of high nutritive value, such as the fig, *date, and banana*, do n[illegible] the highly nutritive su[illegible] foods, it is at least dou[illegible] could be attained by a [illegible] for its chief supply of vegetable food. They all contain an abundance of soluble saccharide, but, with the exception of the banana, are very poor in that most precious of all nutritive ingredients, proteid. Certainly no community, as Payne has shown, has ever attained to any high degree of civilisation which has not cultivated the richly nitrogenous cereals, and these there can be no doubt would never have been cultivated, any more than would the highly nitrogenous pulses which might conceivably have taken their place, had *man remained ignorant of* the art of cookery.

The cibicultural epoch began, say, some 80,000 years ago. One of the first [illegible] food culture was the [illegible] seasons of dearth; a sec[illegible] of plants valuable as food. Both these agricultural foreshadowings are to be observed among the aboriginal Australian pre-agriculturists. Thus they store the bunya-bunya seeds in baskets underground and they have a practice of apportioning to certain families a certain number of the bunya trees which pass on as hereditary property to their children. Man had also learnt to preserve and store animal food—e.g., by drying and smoking—long before he began to breed animals for food. As to whether he cultivated plants or bred animals first is a question we need not discuss just now. In the New World he certainly cultivated plants first. In any case a great forward step was taken when man began to produce food artificially, *when instead of having to search laboriously for fruits*, roots, and seeds he took to cultivating them ready to his hand. He cultivated groves of cocoanut, fig, and date trees, and improved their fruits out of all recognition; he planted large fields of roots, such as the manioc, potato, and yam, and greatly increased their stores of nutriment; and instead of depending for his cereals upon the small seeds of wild grasses collected with infinite labour he diligently tended and promoted their growth and thus developed the noble maize, and still more noble wheat, of which he has eventually come to grow millions of acres. And in regard to the animal kingdom, not only did he learn in the course of time to increase his supply of fish by building vast fleets of fishing vessels to reap the illimitable harvest of the sea, but also in place of spending long hours in the hunt, which at best could yield but a very limited supply of animal food, he learnt to raise on his own account vast flocks and herds of oxen, sheep, goats, and pigs and to breed birds of many varieties. Yet the total effect of food culture has been to make man more vegetarian than carnivorous, inasmuch as the supply of vegetable food has been increased more than that of animal food.

So far as agriculture is concerned the period under consideration falls into two sub-periods: (1) the period of migratory agriculture, in which limited patches of virgin soil were planted and quickly abandoned for new ones; and (2) the period of stationary agriculture, when the ground was carefully tilled, broken up, manured, rolled, and irrigated. During the migratory stage, especially in its earlier part, man still remained a hunter, combining hunting and fishing with desultory agriculture. It is important to distinguish between these two periods, for so long as the human community was wandering and occupied almost entirely with the food quest substantial progress in culture was not possible. It was only when agriculture had become stationary—say some 30,000 years ago—and an abundance of highly nutritious vegetable food and in some cases artificially reared animal food also[4] had been secured by the labour of a limited section of the community, it was only when in this way a large amount of the total energy of the community was liberated and made available for other purposes than the food quest that a complex division of labour became possible. Then it was that civilisation began in real earnest and that the ancient glories of Mexico and Peru, Babylon and Egypt rose in the midst of a barbaric world.

Now we have seen that cookery led the way to agriculture and it may therefore, I think, fairly be claimed for it that it opened the road to all the subsequent great discoveries of man and may thus be regarded as one of his greatest.

The power of digesting raw vegetable foods, which had been steadily waning during the previous diet epochs, has still further declined during the agricultural epoch. Uncultivated vegetable foods have now been practically abandoned and, with the exception of the fruits, very few of the cultivated varieties are eaten in the raw state.

Another effect of agriculture has been greatly to increase the amount of crude starch entering the stomach. We have seen that before the discovery of cooking comparatively *little undigested starch passed into this organ and that* cookery by leading to an increase in the amount of starch ingested and by diminishing the work of mastication and consequently the completeness of buccal digestion led to an increase in the quantity of crude starch passing into the stomach. The introduction of agriculture operated still further in the same direction and augmented the supply of starch to an enormous extent. Within recent times, moreover, it has been the fashion to consume most of the starch in a soft, pappy, or pultaceous form, in the form, e.g., of boiled potatoes, refined bread, porridge, and puddings of various kinds, which readily pass into the stomach after little or no preliminary mastication and insalivation; so that in striking contrast with what happened in the case of early man, the modern stomach is literally deluged with crude starch. This practice among moderns of consuming most of their starchy food in a soft form cannot be too strongly condemned.

(To be continued.)

---

[4] That the artificial rearing of animals was not needful for the attainment of a high degree of civilisation is proved by the case of the ancient Mexicans.

A CHESHIRE COLONY FOR SANE EPILEPTICS.

ON Sept. 8th Mr. B. W. Levy, the David Lewis legatee, formally handed over to representative trustees the title-deeds of the Sandlebridge Colony for Epileptics, between Alderley Edge and Chilford. Mr. Levy handed the title-deeds to the Lord Mayor of Manchester and in the course of his remarks stated that Lord Egerton had consented to be the president of the institution. When the David Lewis Trust decided to establish the colony the experience of the system in England was of the slightest. He therefore visited some of the continental colonies and was so much impressed that he sent a deputation to visit them. The colony now erected was as complete as it could possibly be, "and the object they had in view had been to evolve a colony which would be an object-lesson and act as a guide to those forming similar institutions." The homes were not intended primarily for the pauper classes for whom the guardians of the poor were responsible. The Lord Mayor of Manchester having received the title-deeds expressed his pleasure as chief magistrate of the city in accepting the gift and said that Mr. Levy could not be thanked too much for what he had done. Sir W. H. Houldsworth, Bart., M.P., one of the trustees, in moving a vote of thanks to the Lord Mayor, also spoke of the munificent generosity of Mr. Levy. at the commencement of the trust he had placed £100,000 in their hands for Manchester and a similar sum for Liverpool. He trusted that the public would take care that the necessary funds were supplied for the proper maintenance of the institution. With the example of the well-considered and generous philanthropy of Mr. Levy before them, we may hope that Manchester will not fall short in the duty and privilege of insuring the success of this noble work.

The history of the colony is as follows. In September, 1892, in a paper read before the North-western Poor-law Conference at Chester, Dr. J. M. Rhodes gave expression to a feeling that no doubt existed in the minds of others that as regards any proper provision for sane epileptics England was remiss in her duty. His experience on the Chorlton board of guardians had shown how unhappy was the lot of the sane epileptic, associating as he had to do with the feeble-minded and insane, without provision for amusement or instruction and with the practical certainty that gradually increasing mental feebleness would reduce him to the level of the poor creatures around him. Happily, Dr. Rhodes's paper aroused public attention and in 1897 members of the Chorlton and Manchester asylums committee, including Dr. Rhodes, visited the chief epileptic colonies on the continent. Shortly afterwards, quite independently of the joint asylums committee, a provisional committee was formed with the view of establishing a colony in the Manchester district. This was not connected with the Poor-law but was an independent voluntary association. This committee collected about £8000 which sum was to be the nucleus of an endowment fund. It has now increased to about £14,000, which amount is, however, much too small, but it will grow, it is hoped, to at least £50,000. Application was next made to the Manchester committee of the David Lewis Trust for a grant from its fund. At first this was refused but after searching inquiry the trustees generously offered to provide land and buildings for the proposed colony, to furnish and to equip it, and to hand it over to the committee ready for occupation. When this decision was come to Mr. B. W. Levy himself, as mentioned above, visited some of the continental institutions and sent, moreover, a small commission of inquiry to visit various continental epileptic colonies. It consisted of Dr. Head, Mr. Alexander Graham, architect, and Mr. Levy's own secretary, and reported to him on the medical, architectural, and general aspects of these institutions. Alderman A. McDougall, Dr. Rhodes, and other members of the provisional committee, with the secretary, Mr. Marshall, also visited similar institutions on the continent and in the United States. "These institutions [in the United States] are surrounded by extensive grounds, with farms, workshops, and all that is required by way of healthy surroundings and internal equipment to secure, as far as possible, successful treatment for the unfortunate sufferers." The trustees after some difficulty acquired the Sandlebridge estate, "suitable as regards soil and surroundings." It may be interesting to know that it belonged to Lord Knutsford, whose father, the late Sir Henry Holland, so well known as a scholarly physician, inherited it from his father who lived greatly respected in Knutsford and had a large general practice extending over a wide area. About 130 acres of this estate are immediately available for the purposes of the colony and further land may be brought into use "should the needs or expansion of the colony require it." As the result of all the various inquiries "it was decided to form a colony on the lines of German establishments, with such adaptations and alterations as English climate and modes of life rendered desirable." The buildings consist of an administration block, three houses for men and three for women, each for 20 or 30 patients, a hospital and administration block, school house, chapel, recreation room, kitchen, laundry, farm buildings, and cottages for work-people, and so on. The total cost of land and buildings, together with the laying out of the grounds, electric and sanitary installations, and furnishing, has been over £100,000 and is expected to reach £120,000. The committee will be able to accommodate in the first instance about 200 patients. There is room now, however, for 250 and the hospital and kitchen have been arranged with the view of the number increasing to 500. During the first few years it is expected that there will be a deficiency of income of from £3000 to £4000 yearly. The patients will contribute to the cost of their maintenance at various rates and in years to come it is hoped that a tangible revenue will be derived from the produce of the farm, gardens, poultry yards, and the like, and this hope seems to be justified by the experience of the American institutions of the same character. The education there is such as will assist the epileptic to gain his daily bread. "We must recognise the fact that the epileptic is a more or less defective being," but "there is no reason why he should be a total burden to the State." "For him labour is a godsend and he should be taught how and where that labour can best be used." And the incurables who must always remain at the colony should be able to enjoy reading and to write home to their friends. Many trades and occupations are taught in these institutions besides farming. Thus in the Craig Colony in New York State there are a printing office, a blacksmith's shop, a carpenter's shop, a sewing room, a tailor's shop, and a shoe shop. It should be noted that six hours a day is the limit of work time. In some such ways will the profitable education at Sandlebridge be conducted. In the United States models, pictures, and the Sloyd system are much used. And in such institutions the quality and capacity of the brain have to be considered.

There can be no question that this epileptic colony will meet a great want in a wide district in an efficient manner and the committee, though it anticipates that the colony will in time be to a certain extent self-supporting, is justified in making an earnest appeal for substantial assistance at the outset of its career of usefulness. As previously stated, an effort is being made to raise an endowment fund of £50,000. Dr. Rhodes would double this, his view being that as the proportion of epileptics to the whole population is 1·5 per 1000 the sum of £100,000 is not too great. It must not be forgotten that there will be substantial gain to the community if the care and protection of the epileptics and feeble-minded are carried out in the country at large. The workhouses will be relieved. At present it appears that the only institutions of this kind in this country are at Maghull, near Liverpool, at Chalfont St. Peter in Buckinghamshire, the Countess of Meath's home at Godalming, and a home for pauper Roman Catholic children at Bishop Stortford. There is room for many more but as the law stands at present they must be left to voluntary effort. The county councils can provide for cases of mental disease, but in the eye of the law epilepsy is not a mental disease and cannot be dealt with till it has merged into insanity and the mischief has become complete and irremediable. How desirable it is that care and treatment should begin early is shown from the fact that the prospect of benefit, and even in some cases of cure, is so much the more likely. But even if incurable the epileptics will live under happier conditions than in the miserable homes from which many of them come. They will be saved from themselves and their own weaknesses and from the deteriorating moral and physical influences of the workhouse ward, where too often the sane and the insane, the virtuous and the vicious, are equally hopeless and equally wretched, A great debt of gratitude is due to the David Lewis trustees for their generous and well considered munificence It is intended to make the Sandlebridge Colony one of the best of its kind and it may be hoped that it will be the precursor of others, to surpass, it in usefulness e trustees —Mr B W Levy, V H Mather, Mr S Levy, Mr H Philips, Mr W J Crossley the Lord Mayor of Manchester, the Mayor of Salford, Sir Frank Forbes Adam, Mr H Agnew, Mr E Tootal Broadhurst Mr E Donner, Mr S L Helm, Councillor J Royle, and Mr G Combes The deed provided that the trustees should never number more than 20 The following form the committee of management —Mr R Armistead Mr E Aston Mr A Crewdson Colonel Dixon Mr James Hall Mr S L Helm, Sir Bosdin F Leech Mr Eliot S Levy, Mr E G Leycester Alderman M Dougall, Mr John Royle, Alderman J Milson Rhodes Mr John Shillito Mr Charles H Scott, and Mr Charles E Thornycroft Mr S L Helm is the treasurer

ASYLUM REPORTS

Warwick County Asylum (*Annual Report for 1903*) —The average number of patients resident during the year was 979 comprising 422 males and 557 females The admissions during the year amounted to 239—viz , 111 males and 128 females Of these, 199 were first admissions Dr Alfred Miller, the medical superintendent, states in his report that dmitted was decidedly state More especially Our infirmary wards have been crowded owing to this fact and the amount of extra diet issued has been far greater than in previous years Intemperance in drink was found to exist in 50 of the admissions The number of cases discharged as recovered during the year amounted to 73—viz 32 males and 41 females, or 7 5 per cent of the average number resident The deaths during the year amounted to 105, or 10 7 per cent , as calculated on the same basis Of the deaths five were due to pneumonia, six each were due to cardiac disease and senile decay, ten to epilepsy, 11 to general paralysis 14 to cerebral hæmorrhage, 17 to pulmonary and other forms of tuberculosis, and the rest to other causes The male *patients have as a rule, enjoyed good health, but on the* female side of the asylum there has been a great deal of illness, including an epidemic of diarrhœa About 60 patients were attacked and of these two died "There has been a good deal of discussion, says Dr Miller, "concerning accommodation for idiot and imbecile children certifiable under the Lunacy Act I am sure that these cases are not suitable for the wards of a county asylum I trust that the asylum authorities in the Midlands will combine for the purpose of providing accommodation for the idiot and imbecile children at present in the wards of the county asylums Personally, I would prefer to see these patients classified and living in small numbers, somewhat on the lines of cottage homes Under these circumstances classification would be an easy matter, and those capable of receiving instruction and deriving benefit from special treatment would thereby obtain the best opportunities for doing so ' A new building for private patients has been recently opened and is expected to prove useful 'for a class of patients for whom practically exists in the country" The been entirely remodelled but the end of the year 1904 it is expected that all the wards in the asylum will be plastered and refloored The Commissioners in Lunacy state in their report that the condition of the patients was satisfactory and that they looked well cared for, that they seemed contented and had no complaints to make, that the wards were bright and well ventilated, and that the medical case books and records were efficiently kept The committee of management states in its report that a contract has been entered into for the enlargement of the asylum in accordance with the plans which have been approved by the council for the sum of £6950

Lanark District Asylum (*Report for the Year ending May 15th, 1904*) —The average number of patients resident during the year was 877, comprising 446 males and 431 females The admissions during the year amounted to 223—viz , 120 males and 103 females Of these 129 were first admissions Dr Neil T Kerr, the medical superintendent, states in his report that the number of private patients admitted during the year was again large "and showed the need that existed of granting to district asylums the privilege of admitting private patients at a low rate of board, as has already been granted to English county asylums There are many people in a good social position who frequently find it difficult to pay the higher rate at a private or royal asylum if the relative s illness is likely to be of long duration ' The condition of many of the patients mental and physical, was very unsatisfactory, "indeed," adds Dr Kerr, 'many were hopeless from the very first ' Eight were admitted over 70 years of age It was a matter of regret that so many patients were certified because of the brain failure that accompanied old age, for the accumulation of such senile cases had much to do with the apparent increase of insanity The admissions also included seven cases of congenital mental deficiency, five cases of epilepsy, 11 of general paralysis, and 24 who had attempted suicide prior to admission Of the causes of insanity hereditary predisposition and alcoholic intemperance were the principal ones The number of patients discharged as recovered during the year amounted to 92—viz 61 males and 31 females—or 10 5 per cent of the average number resident The deaths during the year amounted to 73 or 8 3 per cent as calculated on the same basis Of the deaths one was due to renal disease, five were due to general paralysis six to cerebral hæmorrhage, eight to pulmonary and other forms of tuberculosis, 12 to pneumonia and broncho pneumonia, 19 to cardiac disease, and the rest to other causes During the winter there was much illness chiefly influenza, which affected both patients and officials 'It was the most severe epidemic we have had since the asylum was opened and it caused the death of a large number of patients, mostly old and chronic cases who had no reserve [strength] to withstand the virulence of the attack The disease first of all assumed the gastro intestinal type, after a time this type gradually abated and lung complications then became most prevalent The Commissioners in Lunacy state that the meals were excellently cooked and the amount of food was ample for the requirements of the patients The patients were neat and well dressed, their general behaviour was quiet and proper the asylum was found to be in excellent order throughout the wards and dormitories were scrupulously clean and properly heated and ventilated, and the medical case books were correctly and well kept The committee of management *states in its report that additions* and improvements have been made to the dining rooms of the male and female attendants and that a system of electrical fire alarm has been introduced which gives exact information at the central fire station as to the block and the position of a fire

Joint Counties Asylum Carmarthen (*Annual Report for 1903*) —The average number of patients resident during the year was 647 *comprising* 321 males and 326 females The admissions during the year amounted to 177—viz , 103 males and 74 females Of these 160 were first admissions Dr Edwin Goodall the medical superintendent, states in his report that in 65 of the admissions there was ascertained a history of insanity or allied mental disorder in the parents Shock trouble and worry were present as exciting causes in 31 cases Alcohol was assigned as the cause of insanity in 20 cases or 13 4 per cent , "a lower proportion than usual A low proportion [of alcoholic insanity] was also noted last year Among the admissions special reference is made to the case of a father with his two daughters, all received together 'Such cases of so called communicated insanity are rarely seen The circumstances predisposing to their development existed in this instance, neurotic degeneration in the family, lonely surroundings, unusual anxiety, stress of mind among those attacked and a terrifying suddenness of onset in the first case Another curious feature was that death occurred in the same way and from the same cause in two of the cases ' Of the admissions 33 were actively suicidal and 22 were dangerous 89 cases, or 60 per cent of the admissions were attacked with insanity for the first time, which was in itself a favourable circumstance from the point of view of treatment of about 50 cases, since these were admitted to the asylum within three months of the attack In the previous year s report reference was made to a patient admitted for the fifth time in consequence of excess in drink

"Two other such cases," adds Dr. Goodall, "have occurred this year. Such persons in the interests of the community and of themselves should be kept for a prolonged period, or permanently if desirable, in an inebriate reformatory. Even when they happen to be suitable cases for an asylum they cannot be detained in such an institution, for legal reasons, for a sufficient period. This method of dealing with such cases is expensive and inefficient and ought to be done away with. ...... It is high time that reformatories in sufficient number were forthcoming, high time also that the powers of the law in regard to compulsory committal of chronic inebriates were enlarged." The number of cases discharged as recovered during the year amounted to 44—viz., 19 males and 25 females, or 6·8 per cent. of the average number resident. The deaths during the year amounted to 65, or 10 per cent. as calculated on the same basis. Of the deaths two were due to senile decay, three to cardiac disease, five to renal disease, six each to epilepsy and pneumonia, eight to general paralysis of the insane, 15 to pulmonary and other forms of tuberculosis, and the rest to other causes. The Commissioners in Lunacy state in their report that the day-rooms and dormitories were bright, cheerful, and in good order, that the dietary was of good quality, and that the medical case-books were well and carefully kept. The committee of management states in its report that the charge for the maintenance of patients is 9*s.* 0¼*d.* per head per week. The committee has in preparation, by the medical superintendent, a report of a scheme for superannuation of the officials and servants in the asylum service which it is expected will come immediately before the committee for consideration.

County and City of Worcester Asylum (Annual Report for 1903).—The average number of patients resident during the year was 1163, comprising 527 males and 636 females. The admissions during the year amounted to 221—viz., 99 males and 122 females. Of these, 182 were first admissions. Mr. G. M. P. Braine-Hartnell, the medical superintendent, states in his report that hereditary and family predisposition to insanity was the cause in 26·6 per cent. of the admissions, while intemperance in drink was the cause in 15·3 per cent. Of the 221 admissions 201 were in bad or indifferent health with exhausted or reduced bodily condition. The number of patients discharged as recovered during the year amounted to 104—viz., 39 males and 65 females, or 8·9 per cent. of the average number resident. The deaths during the year amounted to 94, or 8·08 per cent. as calculated on the same basis. Of the deaths five were due to cardiac disease, six each to epilepsy and general paralysis, 11 to colitis, 20 to senile decay, 21 to pulmonary tuberculosis, and the rest to other causes. An inquest was held during the year on the death of a patient due to hæmorrhage from rupture of the œsophagus caused by a piece of bone. "The patient had tried to swallow a part of a rib of beef measuring four and a half inches by one and a quarter inches. This got impacted in the œsophagus, causing rupture of the muscle. He complained of no pain and took his food without any discomfort." With the exception of the above case no other accidents during the year were fatal. Four patients escaped and were all recaptured in a short space of time. During the year four nurses and seven female and five male patients were attacked with scarlet fever, there being two deaths. Dysentery was present throughout the year. External iron staircases have been provided in several wards as additional exits in case of fire. "All the exit doors are regularly and frequently opened and the patients exercised in the use of the staircase. 14 of the external doors which opened inwards have been altered to open outwards." Electrical communication has been made from each ward to the porter's room for use in case of fire. The Commissioners in Lunacy state in their report that the rooms and dormitories were clean and in good order as were also the beds and bedding, that the dress of the patients was neat and varied, that there were no complaints as to their treatment, that the meals served were of a substantial character, and that the medical case-books were carefully and intelligently kept. Though the general health of the patients appeared to be good the Commissioners regard the sanitary condition of the asylum as open to improvement owing to the number of cases of scarlet fever, dysentery, and measles that have occurred during the year. The committee of management states that it has been compelled to raise the rate of maintenance for patients to 8*s.* 5½*d.* per head per week.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Reinspection of the Borough of Whitehaven and on recent administration therein, by Dr. R. FARRAR.[1]—This report gives an account of an inspection made to ascertain the work of the town council of Whitehaven since that borough was inspected in detail by Dr. H. T. Bulstrode in July, 1902. Dr. Bulstrode's report was of interest from the discussion given to various aspects of the housing question. In the eighteenth century Whitehaven was a well laid-out town with wide streets and well-built houses, having each a strip of garden of the width of the house at the back. When owing to the development of collieries the town increased in population and it was found impossible to obtain land for building from the lord of the manor outside the limits of the town owners of house property ran up blocks of back-to-back houses in what originally were gardens. Later the interstices between these blocks and original houses were filled up with smaller tenements, wedged in wherever room could be found. The houses in the courts thus formed are without any proper supply of air or light and in various other respects are objectionable. Dr. Bulstrode was obliged to report that in many cases nothing short of their demolition would suffice to remedy the unhealthy conditions which obtained in the town. Since his report in 1902 the town council has effected an important number of sanitary reforms in various directions for which it deserves credit. But it has so far done little to deal effectively with the main question of better houses. What effort has been made has rather tended to perpetuate the objectionable conditions which the presence of many of the courts makes inevitable. Dr. Farrar now advises the provision by the local authority of a number of cottages of appropriate construction outside Whitehaven and the demolition of a corresponding number of "slum houses" in the centre of the town. This recommendation admittedly deals with only a portion of the difficulty but it is obvious that a large scheme of demolition and new building would involve a much larger expenditure than Whitehaven could afford. Dr. Farrar urges, however, that much good might be done by the judicious selection of even a small number of houses for demolition under the Housing of the Working Classes Act. Dwelling accommodation would need to be provided for the persons displaced and Dr. Farrar suggests that this might be done by the coöperation of the town council and the local colliery company, many of whose workmen at present live in the unhealthy slums of the town.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8544 births and 5118 deaths were registered during the week ending Sept. 10th. The annual rate of mortality in these towns, which had been 22·7, 20·5, and 18·2 per 1000 in the three preceding weeks, further declined last week to 17·5 per 1000. In London the death-rate was 15·2 per 1000, while it averaged 18·5 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 5·1 in Hornsey, 8·3 in Willesden, 8·6 in Smethwick, 9·4 in King's Norton, 9·6 in Handsworth (Staffs.), 11·7 in Walthamstow, and 12·8 in West Hartlepool; while the highest rates were 24·7 in Liverpool, 25·0 in Rotherham, 25·3 in St. Helens, 26·5 in Tynemouth, 28·4 in Plymouth, 29·9 in Wigan, 31·8 in Hanley, and 33·0 in Great Yarmouth. The 5118 deaths last week included 1512 which were referred to the principal infectious diseases, against 2841, 2291, and 1636 in the three preceding weeks; of these 1512 deaths, 1258 resulted from diarrhœa, 64 from whooping-cough, 63 from diphtheria, 53 from measles, 47 from "fever" (principally enteric), 23 from scarlet fever, and four from small-pox. No deaths from any of these diseases was registered last week in King's Norton; among the other towns they caused the lowest death rates in Hornsey, Hastings, Brighton, Norwich, Handsworth (Staffs), Smethwick, Bury, Halifax, and Newport (Mon), and the highest rates in Portsmouth, Great Yarmouth, Plymouth, Hanley, Stockport, Liverpool, Bootle, Wigan, and Burnley The greatest proportional mortality from measles occurred in Plymouth, Walsall, and Stockport; from diphtheria in Hanley, Bootle, Bradford, and West Hartlepool, from whooping-cough in Great Yarmouth, West Bromwich, and Stockport, from "fever" in *Aston Manor*, *and from diarrhœa in* Great Yarmouth, Plymouth, Hanley, Grimsby, Liverpool, Bootle, Wigan, Burnley, Preston and Hull The mortality from scarlet fever showed no marked excess in any of the large towns Two fatal cases of small-pox were *registered in Salford, one in Manchester, and one in New*castle on Tyne but none in any other of the 76 towns The number of small pox cases in the Metropolitan Asylums Hospitals, which had been 18, 13, and nine on the three preceding Saturdays, had further declined to eight on Saturday last, Sept 10th, two new cases were admitted during the week, against two none, and two in the three preceding weeks The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 1745, 1781, and 1819 at the end of the three preceding weeks, had declined again to 1816 at the end of last week, 234 new cases were admitted during the week, against 198, 263, and 266 in the three preceding weeks The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 106, 101, and 108 in the three preceding weeks, further rose last week to 129 and were six above the number in the corresponding period of last year The causes of 48, or 0 9 per cent, of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham Portsmouth, Hull, Newcastle on Tyne, Cardiff, and in 46 *other smaller towns*, *the largest proportions of uncertified* deaths were registered in Birmingham, Liverpool, St Helens, Manchester, Preston, Sheffield, South Shields, and Gateshead

---

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns, which had been 15 7, 16 2, and 16 0 per 1000 in the three preceding weeks, further declined to 15 7 per 1000 during the week ending Sept 10th, and was 1 8 per 1000 below the mean rate during the same period in the 76 large English towns Among these Scotch towns the death rates ranged from 9 7 in Leith and 14 0 in Edinburgh to 18 7 in Greenock and 20 0 in Perth The 519 deaths in these towns included 52 which were referred to diarrhœa, 17 to whooping cough, five to measles, five to diphtheria, five to "fever," and two to scarlet fever, but not any to small pox In all, 86 deaths resulted from these principal infectious diseases last week, against 94 97, and 100 in the three preceding weeks These 86 deaths were equal to an annual rate of 2 6 per 1000, the death rate last week from the same diseases in the 76 large English towns being 5 2 per 1000 The fatal cases of diarrhœa, which had been 66, 56, and 58 in the three preceding weeks, declined again last week to 52 of which 22 occurred in Glasgow, nine in Dundee seven in Edinburgh, seven in Paisley, four in Greenock, and three in Aberdeen The deaths from whooping-cough, which had been 16, 24, and 26, declined again to 17 last week and included nine in Glasgow, three in Edinburgh, two in Dundee, and two in Greenock The fatal cases of measles, which had been ten and four in the two preceding weeks, rose again last week to five, of which four were registered in Glasgow The deaths from diphtheria, which had been one, one, and four in the three preceding weeks, further rose to five last week, and included two in Glasgow and two in Edinburgh The fatal cases of "fever," which had been two and six in the two preceding weeks, declined again last week to five of which two belonged to Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had been 47, 55, and 53 in the three preceding weeks rose again last week to 58 and were slightly in excess of the number in the corresponding period of last year The causes of 16, or more than 3 per cent, of the deaths in these eight towns last week were not certified

HEALTH OF DUBLIN

The death rate in Dublin, which had been 24 5, 23 5, and 19 9 per 1000 in the three preceding weeks, rose again to 20 8 per 1000 during the week ending Sept. 10th. During the past four weeks the death rate has averaged 22 2 per 1000, the rates during the same period being 18 0 in London and 14 4 in Edinburgh The 151 deaths of persons belonging to Dublin registered during the week under notice were six in excess of the number in the preceding week and included 32 which were referred to the principal infectious diseases, against 43, 49, and 29 in the three preceding weeks, of these, 26 resulted from diarrhœa, four from whooping cough, one from measles, and *one from "fever,' but not any from small pox, scarlet* fever, or diphtheria These 32 deaths were equal to an annual rate of 4 4 per 1000 the rates during the same period from the principal infectious diseases being 3 5 in London and 2 2 in Edinburgh The fatal *cases of diarrhœa, which had been 33, 35, and 26 in the three* preceding weeks, were again 26 last week The deaths from whooping cough, which had been three, four, and one in the three preceding weeks increased again last week to four The 151 deaths in Dublin last week included 51 of children under one year of age and 34 of persons aged 60 years and upwards, the deaths of infants corresponded with the number in the preceding week, while those of elderly persons showed a slight increase One inquest case was registered but no death from violence was recorded, 48 or nearly one-third, of the deaths occurred in public institutions The causes of six, or nearly 4 per cent of the deaths registered in Dublin last week were not certified

Looking Back.

FROM

THE LANCET, *SATURDAY*, SEPT. 16, 1826.

THE ZOOLOGICAL SOCIETY

THERE are some departments of science in which our continental neighbours have made much greater progress than ourselves, and, singularly enough, this has happened more particularly in a certain branch, in which, from our local and commercial advantages, we ought to have been the precursors

Zoology which, as a matter of study, offers peculiar attractions, as illustrating the most interesting series of Nature s laws and as connected with the history of almost an infinity of
of mankind, l
public encour
even in lazy
governments with a liberality which does them honour

We are glad to see that an Institution has at length been formed in this country for the prosecution of so interesting and useful a branch of study, and hope that it will receive that patronage which it deserves from an enlightened, and more especially from the medical public

At present the Zoological Society is the offspring of a union of individuals, and has received as yet no support from the government, which has usually shown itself ready to follow, never to lead the public opinion Previously to the meeting in April last, nearly three hundred persons had signified their intention of becoming members, and *among* these were names distinguished in science, rank, and affluence Since that period, about a hundred additional names have been subscribed, and the interest excited in favour of the Society, appears to be still on the increase A house has been taken in the most central part of western London, which is now preparing for the reception of the collections already placed at its disposal, and it is expected, that in a short time nearly two thousand species of the mammalia and birds, a number exceeding that in the British Museum, will be ready for exhibition But the views of the Society extend beyond the preservation of the stuffed skins and lifeless bodies, they embrace the maintenance of living animals Ground has been obtained for this purpose in Regent s Park, in which aviaries and enclosures of various kinds are to be formed, and a
most c
for its
been completed To this collection the members of the Society will have access as a matter of right [1]

---

[1] Excerpts from editorial observations

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointment is announced :—Fleet Surgeon S. W. Vasey to the *Defiance*.

Fleet Surgeon John Henry Thomas has been placed on the Retired List at his own request.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel P. M. Ellis to be Colonel, vice R. Blood, M.D., retired.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Aberdeen Company: Major J. S. Riddell to command under paragraph 55A Volunteer Regulations.

HONOURABLE ARTILLERY COMPANY OF LONDON.

Surgeon-Major T. E. F. McGeagh resigns his commission, with permission to retain his rank and to wear the prescribed uniform, and retires into the Veteran Company. John Francis Taylor to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers) : 1st Forfarshire: Surgeon-Lieutenant W. A. Taylor to be Surgeon-Captain.

Rifle: 2nd Volunteer Battalion the King's Own (Royal Lancaster Regiment): Surgeon-Lieutenant B. W. Hogarth to be Surgeon-Captain. 3rd Volunteer Battalion the Cheshire Regiment: Surgeon-Lieutenant T. A. Rothwell to be Surgeon-Captain. 3rd (Sunderland) Volunteer Battalion the Durham Light Infantry: William Byron Milbanke to be Surgeon-Lieutenant.

The King has been graciously pleased to approve of the Bearer Company of the Lancaster and Border Volunteer Infantry Brigade being formed into an independent unit, to be designated the "Lancaster and Border Bearer Company, Royal Army Medical Corps (Volunteers)."

PULMONARY TUBERCULOSIS IN THE ARMY.

According to a recent order of Lord Kitchener, the Commander-in-Chief in India, all soldiers of the British Army serving in his lordship's command who are suffering from pulmonary phthisis are in future to be invalided home at once instead of being treated, as has hitherto been the case, at the local sick quarters and hospitals throughout his command. In consequence of this order the Indian mail steamer *Arabia*, which arrived at Plymouth on Sept. 11th, brought home 22 of such military invalids from Bombay. It goes without saying that the medical authorities in India might, if only in the interest of the sufferers, have to retain a few phthisical patients who, however desirous they themselves were of encountering any risk in order to get home, might yet be so manifestly unfit to undertake the journey that it would be cruel to let them make the attempt. Patients suffering from pulmonary consumption do not, as a rule, progress favourably in such a hot and enervating climate as that of India and there is no reason therefore, even apart from the fact that they only serve to swell the sick and inefficient list, why they should be retained there for treatment. They would, on the contrary, probably do better in this country, but we think that, speaking generally, care should nevertheless be taken in regard to the selection of such patients, as well as in taking advantage of the best season for sending them home, in order to avoid their landing in this country in midwinter or at the beginning of the cold weather, with its discomforts and risk of the patients contracting inflammatory lung complications. With our more precise knowledge of the causes of this disease and its modern systems of treatment, both prophylactic and curative, broadly based on hygienic principles we have made a great stride in advance. So far as we know, no separate provision has been yet made, however, in the army for the special accommodation and treatment of these cases in all their stages in accordance with existing views but such provision will have to be made. In the meantime there are many newly constructed army hospitals to be found, in the Isle of Wight, for example, and elsewhere, which, in point of climate, open and healthy sites, accommodation, and appliances, are well adapted and might be utilised for this and similar purposes. It seems a pity that the advantages which they offer should be restricted to the relatively small number of sick labouring under ordinary and often trivial ailments drawn from the troops in their immediate locality. There seems to be no reason why cases of phthisis should not obtain in such places all the benefits of isolation and open-air treatment, while soldiers convalescing from other diseases might, with proper precautions, reap the advantage of all the air and sunshine obtainable in this country.

DEATHS IN THE SERVICES.

Surgeon-General James Jameson, M.D. Glasg., C.B., honorary surgeon to the King, late Director-General of the Army Medical Service, at Newlands, Eltham, on Sept. 13th, aged 67 years. Surgeon-General Jameson graduated as M.D. at the University of Glasgow in 1857 and entered the army as assistant surgeon in November of that year. He was Director-General of the Army Medical Service from May, 1896, to September, 1901, when he was succeeded by Surgeon-General Sir William Taylor, K.C.B. It was during Surgeon-General Jameson's tenure of office that the Royal Army Medical Corps was constituted.

Surgeon-Major John Campbell, C.B., late of the Indian Army, at his residence, The Quarry, East Looe, Cornwall, on August 26th, in his eighty-seventh year. The deceased was born at Looe on April 27th, 1817, being the youngest son of Captain Thomas Campbell, R.N. He entered the Indian Army as a medical officer and during the first Afghan war in 1841 he served with the troops marching from Jerezepore towards Cabul. He was with Wylder's Brigade at Peshawar and in its ineffectual attempt to force the Khyber Pass and to join General Sele, who was at Jellallabad. He was also with the army under General Pollock which marched through the Khyber Pass to Cabul. During the suppression of the Indian Mutiny he was again actively employed and for his services at the siege of the Residency at Lucknow was created C.B. in November, 1858. He retired from the service in 1864 and took up his residence at Looe, where he soon became extremely popular owing to his many acts of kindness.

ARMY REFORM.

We seem to be as far off as ever from reaching any really large, effective, and satisfactory measure of army reorganisation and reform. The more the present War Minister's proposals in this direction are scrutinised and considered the greater seems to be the growth of misgiving in regard to them. That the new scheme embodies many sound and excellent principles is admitted but further and fuller explanations and details are required. The recruiting question lies at the root of the problem and there is no well-grounded assurance that this has yet been solved. It must be allowed that we were able during the late war in South Africa to put a large force in the field in a relatively short space of time, but it seems doubtful whether the newly proposed "striking force" to be kept ready for war purposes is sufficiently large for the object in view and the question arises as to how it is to be kept up during war. With no representative of the medical and sanitary needs of the army on the Army Council it is difficult to see how they are to be satisfactorily dealt with, and to lower the age of young soldiers intended for service in India below what it is now appears to be, as we have previously said, a retrograde step in army hygiene.

THE WAR IN THE FAR EAST.

At the moment of writing there is a temporary lull in the warlike operations in the Far East owing to various causes. The belligerents of both sides are exhausted by the very hard and almost continuous fighting which has been taking place, by the hardships, want of food, and fatiguing marches which the troops have had to encounter, well-nigh rendering further efforts on their part a physical impossibility, and by the reappearance also of torrential rains making the roads impassable for transport. Both armies are simply worn out by their terrible exertions, but no pause is, nevertheless, taking place in the hurrying up of strong reinforcements in order to renew the encounters at the earliest opportunity. Although General Kuropatkin has been unable to ward off the very heavy blow which has been struck at the prestige of his country he has succeeded in maintaining, and even in adding to, his military reputation by his masterly if terrible retreat from Liaoyang. The main facts regarding the object, nature, and extent of the fighting in and around Liaoyang have now been made sufficiently clear to enable us to form a fairly accurate idea of what has taken place. If the Japanese have failed in securing the great object which they had in view they have nevertheless defeated and caused the retreat of the Russians from an extremely strong and commanding position And if General Kuroki s army after the severe fighting at Hai yen tai—which was the Spion Kop of the operations—was too exhausted to follow up and "to head off " the enemy before reaching Mukden it still remains to be seen whether this cannot be done somewhere beyond that position As regards the casualties on the two sides there is as might be expected, some difficulty in forming a correct estimate, but there can be no doubt that they were very heavy on both sides The difference, it must be remembered, of a single day in collecting the returns of the casualties will cause an important difference in the sum of the number wounded on a given occasion The Japanese official estimate of their total casualties in the Liaoyang fighting amounts to 17,539, and they state that they buried over 3000 Russians on that occasion and that over 10 000 killed and wounded are estimated to have been sent off by train The Russian official estimate of their losses at Liaoyang is practically given as about the same as the Japanese—that is to say, over 17,000, including 4000 killed But there can be no doubt that it was much larger than this (probably over 25 000 from the day of the evacuation of Anshanchan to the fall of Liaoyang) Unofficial estimates at St Petersburg put the Russian losses in and around Liaoyang and during the retreat to Mukden as even reaching 40,000 Those who are desirous of ascertaining the numbers and proportions of killed, wounded and missing in various battles will find a good deal of information thereon in Longmore s 'Gunshot Injuries (Longmans Green and Co , 1895) and in his treatise on "Ambulance Transport publi hed by the War Office From all that we read and hear it seems clear that not only must the belligerent armies in the field have been exposed to great hardships, excessive toil, wet, and famine but from the fact that the number of sick and wounded was so great these must have undergone a very lamentable time of neglect and suffering We hear but little of the sickness on either side This must in the circumstances be considerable It is stated that the Japanese troops besieging Port Arthur have many cases of beri beri among them Despite the very best efforts of medical administration it is simply impossible to deal promptly with such overwhelming conditions as have of late presented themselves It is not surprising to learn, therefore that the scenes on the battle fields were often appalling The Japanese Red Cross Society which has usually worked in an admirable way, proved unequal to the unprecedented strain put upon it and many of the wounded succumbed for lack of timely attention With the Russians conditions are stated to have been infinitely worse The medic

are assisting the surgeons

belligerents All the Russian

to have been sent north from Mukden The troops are distributed in positions around the town

The siege of Port Arthur is proving a far harder task than had been anticipated Its fall would liberate a large Japanese force for taking part in the field operations elsewhere Unhappily there does not appear to be any near prospect of an end to the war Both sides are making stupendous efforts to carry it on and there are no present hopes that any attempts at mediation would be of any avail

Correspondence.

"Audi alteram partem."

THE NATURE AND ETIOLOGY OF CANCER

To the Editors of THE LANCET

SIRS,—In your leading article on the Nature and Etiology of Cancer in THE LANCET of August 13th, p 473 you say 'Let those who in future essay to advance our knowledge of cancer regard it as their first duty to add *new facts* to those long known I agree with Mr T W Nunn in hoping that the remarks you have made on this subject may induce medical men to see the importance of inquiring into and recording actual facts rather than formulating new theories of which we already have a superabundance In my opinion a most important point for further investigation is the relationship between tubercle and cancer I hold most strongly that in every case of cancer careful inquiries should be made into the family history of consumption

Roger Williams was I believe, the first to draw attention to this point, for which sufficient credit has not been given him In his book on "Diseases of the Breast, with special reference to Cancer, ' he remarks 'No hereditary condition is more favourable to the development of cancer than that which predisposes to and accompanies tubercle ' Amongst his cases of mammary cancer he found there was a family history of consumption in 55 per cent I found it in 39 per cent of my own As 19 per cent may be taken as the average of a family history of consumption amongst the general community it is evident that as far as our two sets of statistics go the proportion is much increased in cases of mammary cancer In addition to the case mentioned in my book where a youth aged 23 years, who had lupus of the face and nose, developed an epithelioma of the upper lip after being subjected to the x rays for three occasions only, I notice that in THE LANCET of June 11th p 1659, Dr Norman Walker at a meeting of the Edinburgh Medico Chirurgical Society reports three apparently similar cases and in one of these the epithelioma developed *before* the application of the x rays Surely these *facts* point to an intimate relation between tubercle and the development of malignant disease and show the necessity of carefully inquiring into the actual presence of or predisposition to tubercle in all future investigations

or

that you think that 'similar

in respect to cancer in other regions of the body might be instituted with advantage, ' as it corroborates my view that as a preliminary to the study of the etiology of cancer each region where it occurs should be studied separately We are not justified in assuming that cancer is always due to a single cause or that it is necessarily the same in the different regions I would urge the discontinuance of the terms predisposing cause and actual cause We have at present no means of differentiating between the two and few are agreed as to what should be considered a predisposing and what an actual cause In fact, the use of these terms is misleading and presuppo es a knowledge we do not at present possess It induces many pathologists to investigate only along those lines which they imagine will lead them to the attractive discovery of the so called actual cause and to neglect or to hold of little value those simple but somewhat dry facts which I think, must prove the foundation stone on which the greater part of the etiology of cancer—at any rate in the human subject—will eventually be laid I am Sirs yours faithfully,

Wimpole street W August 29th 1904 CECIL H LEAF

INDIRECT SPECIFIC INFECTION THROUGH THE ALIMENTARY TRACT IS THE IDEA CONCEIVABLE?

To the Editors of THE LANCET

SIRS —May I through the medium of your columns draw the attention of the profes ion to the possible risk of indirect specific infection through the alimentary tract after operation I am well aware that many consider the above mentioned phenomenon to be inconceivable on the ground that should specific organisms or toxins be ingested the antiseptic action of the alimentary secretions is sufficiently powerful to destroy or to neutralise them

Some months ago I had the opportunity of assisting at an operation for flat foot and as this, I think, is a case in point I will make no apologies for mentioning the matter The operation was conducted with due regard to efficient asepsis and the patient so far as was known had no organic disease before the operation and showed a fair history The primary operation wound healed by first intention and went on well for a week At this period he complained of feeling unwell and displayed a temperature of 99° F The next thing observed was redness œdema and di comfort at the closed wound which was immediately opened up and disclosed a small quantity of pus I examined this pus and was able to demonstrate tubercle bacilli Feeling convinced that this specific condition was in some way connected with the simple operation I made every possible inquiry and examination and at last was able to demonstrate a case of tuberculous mastitis in a cow which belonged to the herd supplying the nursing home where the operation took place. Bearing in mind Kipling's story of the war correspondent and the sea serpent I refrained at the time from doing more than indicating my views to the surgeon in charge of the case. Lately I have been planning a series of ingestion experiments with a view to threshing the matter out thoroughly. Should the suggestion prove not to be fallacious it is easy to foresee elementary prophylaxis would demand the "Pasteurisation" of all food for at least a week after operation. With regard to research in this direction, I should esteem it a favour if any of your readers could suggest literature bearing on the point. Klein omits to refer to the matter, also Woodhead. Sternberg, I think, passes it by. Also our most able exponent of asepsis fails to mention the possibility of the idea in his invaluable monograph on Aseptic Surgery.

I am, Sirs, yours faithfully,
Lancelot Wilkinson.

St. Bartholomew's Hospital, London, Sept. 5th, 1904.

PHIMOSIS AND HERNIA.

To the Editors of The Lancet.

Sirs,—In his lecture on the Pathology and Treatment of the Herniæ of Children, published in The Lancet of August 20th, p. 511, Mr. Edred M. Corner refers to the causal relation between phimosis and hernia. He lays most stress in his argument against this theory upon the fact that "the preputial orifice is rarely small enough to be of such paramount importance" and he proceeds to say that "ballooning of the prepuce" would occur and be observed by the nurse. In most cases of phimosis there is usually so much adhesion that ballooning would be impossible. Mr. Corner ignores some other evidence on this subject. The reflex irritation of an ordinary phimosis induces frequent micturition and the amount of straining exerted to empty a bladder with very little in it is greater than that required to discharge one moderately full. Moreover, besides the straining of frequent micturition, the persistent annoyance of a tight prepuce irritates the baby, makes him not only fretful and restless but induces paroxysmal attacks of screaming and these vocal efforts exert no mean amount of pressure on the abdominal walls.

Experienced nurses have repeatedly told me how much less frequent attacks of crying have been after circumcision. Quite recently I have had an opportunity of watching a small inguinal hernia which made its appearance about six weeks after birth completely disappear soon after circumcision. It is true a truss was worn for a few weeks but it was then removed and there has been no recurrence of the hernia up to the present. Among the ancient sanitary laws of the Jews I am inclined to believe that the rite of circumcision was by no means one of least value.

I am, Sirs, yours faithfully,
Uppingham, August 29th, 1904. H. Lyon Smith.

PATENT INFANT FOODS AND THE RISK OF SCURVY.

To the Editors of The Lancet.

Sirs,—The subject of infant feeding is often treated in your columns, forming the substance of lectures, papers before medical societies, and books under review. There are many observers seeking by scientific methods to devise normal physiological foods for infants who are deprived of breast milk. In the meantime we have to deal in practice with such means as are available and to recognise that a large and increasing number of infants are still fed on "sterilised milk," condensed milk, or one of the numerous patent foods which are in the market. That these foods vary greatly in quality and value has been shown, especially by Dr. R. Hutchison,[1] and the careful reader of his excellent address will have no difficulty in distinguishing those that have some claim to be considered as normal infant foods from those the composition of which is altogether unsuitable. Recent works on infant feeding either condemn patent foods *in toto* or admit one or two as perhaps useful in certain conditions.

There is one feature of the use of these prepared foods which has not, I think, had full attention: its relation to the risk of scorbutic disease. Only a few weeks ago[2] Dr. G. F. Still described in The Lancet two cases in which well-marked symptoms of infantile scurvy appeared after feeding with condensed milk and Allenburys and Benger's foods. It is well known that infants in whose dietary "fresh" or living food has no place are liable after the age of six months to the outbreak of this disease. It is also generally agreed that milk loses what have been called in this connexion its "natural living qualities" by heating to the extent necessary for boiling, for producing sterilised or pasteurised milk, and for making so-called "condensed milk." For the same reason those patent foods which belong to the class of desiccated milk and are mixed for use with water only, like the Allenburys (I. and II.), Horlick's, Carnrick's, and Nestlé's foods, form when given alone a diet insufficient to provide against the risk of scurvy. Patent foods directed to be mixed with fresh milk are much less liable to this objection, but if, as in the case of Savory and Moore's, Benger's, Allenburys No. III., and others, the milk is to be boiled, it furnishes no protection against such disease. It is further to be noted that although infantile scurvy is a comparatively rare disease and appears in a developed form only after the age of six months, it is probable that the like disorder may be present in slighter degrees; and that anæmia and poor nutrition, with perhaps tender gums, occurring in many infants at an earlier age may be attributable to a similar though less severe change in the blood. On the other hand, the means of preventing such blood disorder are simple and ready to hand—viz., the administration of a little floury potato, crushed rice, grated banana, raw meat juice, or the juice of orange or grape, besides fresh unboiled cow's milk. The habit of the poor to give to their babies "a little of what we have ourselves" may often disturb their digestion but in my opinion the teaspoonful of potato and gravy from the mother's plate saves many infants fed on condensed milk or on one of the cheaper patent foods from scorbutic trouble. In this way the poor may actually avoid some of the risks attending the stricter feeding practised by the rich.

The object of stating these facts is in order to urge the duty of our profession to show to the manufacturers of sterilised and condensed milk and infant foods the need of clear directions, to be printed upon all their tins and bottles, that after the age of three or four months one or other of the articles of fresh food alluded to should be given in small quantities twice a week in addition to the prepared food. It is necessary, too, that the public should be educated in the same sense, especially as printed instructions are often little read. Some of the best foods are already protected in this way—e.g., the Allenburys, Mellin's, and Benger's—whose proprietors give clear directions to the consumers for the occasional use of fresh diet whilst taking the patent food. It is only fair to state this as it is pretty evident that in Dr. Still's cases the printed advice had been disregarded. I quote from the label on the Allenburys food No. II.:—

> It is advisable, after the first two or three months of life, to give, in addition to the manufactured food of whatever kind, some fresh material, such as grape juice, the sweetened juice from .... an orange, &c.

If these directions were made still more prominent and if the numerous patent foods which at present give no such warning were provided with it I think that the health of a multitude of hand-fed infants would be helped, without waiting for the day, for the coming of which food reformers are working, when a truly normal substitute for human milk in cases where this is not available shall find full acceptance.

I am, Sirs, yours faithfully,
Weymouth-street, W., Sept. 5th, 1904. R. Hingston Fox.

LAYMEN AND ELECTRICAL TREATMENT.

To the Editors of The Lancet.

Sirs,—I trust that you will allow me a little space to reply briefly to Mr. Chisholm Williams and others who have criticised my note on the above subject in The Lancet of August 6th. People have a curious way of misunderstanding or overlooking language the meaning of which appears quite obvious. I specially guarded myself against the idea of handing patients over to "people who pose as healers or who prefer to act apart from medical men." If this quotation from my letter has any meaning it disposes beforehand of all your correspondents virtuous indignation over my supposed advocacy of the support of quacks or quack institutions

---

[1] See The Lancet, July 5th, 1902, p. 5.

[2] The Lancet, August 13th, p. 441.

None of your correspondents have advanced any arguments or stated any facts to support the contention that it needs the skill and knowledge of a qualified medical man to apply electricity in the great majority of conditions in which it is found useful, such as those I mentioned in my previous note I should say that to one case which requires the knowledge and skill of a man like Mr Chisholm Williams there are at least 20 that can be perfectly well treated by a masseur or masseuse who has received the excellent training of the modern teachers of massage and electricity Indeed, I venture to suggest whether it is not somewhat derogatory to the dignity of the profession for a qualified medical man to undertake the routine treatment of such cases

To correct Mr Chisholm Williams s and others' misconstructions of my remark about having one s ideas of diagnosis and treatment overhauled by another practitioner I will narrate a case in point I sent an intractable case of Graves s disease for treatment to a highly qualified medical electrician (who, I believe, charged a guinea for each sitting) Without any thought or intention of breach of faith towards me he rather pooh poohed the idea of using electricity and, of course, absolutely discouraged the patient thereby preventing her giving electrical treatment a trial of sufficient duration to convince me of its value or *otherwise in her case* Had I *sent this patient to* a lay electrician acting under my own instructions she would have continued the treatment as long as I thought it worth while I have no lack of confidence in the good faith of my professional brethren but I contend that skilled knowledge of a special line of treatment does not put the electric practitioner in possession of all one s reasons for desiring a certain line of treatment in a particular case I cannot see any analogy between the case of a non medical but trained person applying electrical treatment when prescribed by a physician and that of a patient being treated by a bone setter or quack oculist Finally I must say that to talk about covering in connexion with my letter—if read with ordinary intelligence—appears to me to be rank absurdity

With regard to the x rays my experience is limited to their use by qualified medical men I am glad to learn from Mr Chisholm Williams that it is possible to get such treatment at a scale of fees within the reach of middle class patients —I am, Sirs, yours faithfully

APOCYNUM CANNABINUM

To the Editors of The Lancet

Sirs —The editorial note on the Uses of Apocynum Cannabinum in The Lancet of Sept 3rd p 734 will I hope, direct the attention of the profession to a remedy which I have found of the greatest value and have constantly prescribed for the last 14 years The drug was first introduced to my notice by Dr Joseph Kidd who recommended me to try it in the case of a patient with dilated heart who had passed from his care to mine when she moved into the country The disease had reached a stage when the patient could no longer rest recumbent the anasarca and ascites being so advanced that paracentesis appeared to afford the only chance of relief The 'vegetable trocar ' however, answered admirably Within the first two days of its administration the urine rose from about ten ounces in the 24 hours to 60 and the diuresis increased daily until the ascites and the anasarca almost disappeared the patient getting about again and living for two years Again and again I have had similar experience and a large number of my colleagues in this district now employ the remedy having seen such marked benefit from it in cases of cardiac and renal dropsy in which we have consulted

I have always used Keith s concentrated tincture [1] which Dr Kidd recommended as the only reliable preparation of the drug Several of my professional brethren who have employed the tincture usually kept by chemists have been disappointed in its effects, and to the want of activity in this the ordinary tincture must I think be attributed the fact that apocynum cannabinum has not come into more general use The fluid extract recommended by Dr J Pawinski may be equally efficacious with Keith s preparation but of this I have no experience The irritant action of the drug upon the digestive organs is a positive quality which must be borne in mind In the first case in which I so successfully employed apocynum the dose recommended by Dr Kidd who was, at the time, I believe supposed to prescribe drugs in decillionths and similar fractions of their ordinary doses caused violent vomiting and purging and I had at once to reduce it to one sixth the amount In cases of cirrhosis of the liver I have found the smallest doses cause dangerous gastric irritation and I always warn [illegible] against [illegible] in these [illegible] prescribe [illegible] from one to two minims every four hours or three times a day increasing the dose by one minim every two days until the maximum which the stomach and intestines will bear is reached, this is seldom as much as ten minims The medicine may be combined with other heart tonics Employed carefully in this way its beneficial effects have in my own experience and in that of the many friends to whom I have introduced apocynum cannabinum, been astonishing and yet so little is the medicine known that only once, when in consultation I have advised its use has *my colleague* been familiar with it and that man immediately said ' I know where you got that from it was from Kidd

With the precautions which I have indicated I strongly advise your readers in cases of cardiac and renal dropsy to try this remedy the merits of which I have long intended to press upon the notice of the profession through the medium *of your columns*

I am Sirs yours faithfully,

Thomas James Walker, M D Lond

Peterborough Sept. 10th 1904

THE UTILITY OR OTHERWISE OF FEVER HOSPITALS

To the Editors of The Lancet

Sirs —I entirely endorse the view to which Dr C K Millard gives expression in your issue of to day s date that should an inquiry take place the fact of having taken part in this controversy ought to constitute a disqualification for a place on the Commission I agree, also with the suggestion that sanitarians who have been actively instrumental in *securing the provision* of fever hospitals in the *past* should not be placed in the invidious position of having to sit in judgment on their own actions The fact that many able and conscientious medical officers of health will thus be excluded need not be deplored seeing that their evidence will be available and will lose none of its weight Now a word of caution I cannot help thinking that undue haste would be a great mistake *Festina lente!* The reasonable demand that an inquiry should be held has been too grudgingly conceded up to the present time to justify the hope that this important question is ripe for settlement on its merits Let us leave it for a time in the crucible of intra professional discussion where the truth should be in no danger

In conclusion I echo your suggestion Sirs that the controversy may well be conducted without personalities in the future Indeed there is no room for them For whatever *be the outcome of this inquiry* should it take place, it will not be denied that much good has *already* been accomplished which will be a distinct gain to the cause of public health I am Sirs yours faithfully,

Nottingham Sept 10th 1904 Edwd Dean Marriott

THE BOILING OF MILK

To the Editors of The Lancet

Sirs —May I as the iconoclastic scientist referred to by Dr J M Fortescue Brickdale in The Lancet of Sept 10th p 792 offer a word of explanation with regard to the slight misapprehension he is under as to my views on the boiling of milk In the course of my conversation with Mr R Bevan I did not enter on the very debatable ground included under reasons (2),

---

[1] Keith s concentrated tincture of apocynum cannabinum may be obtained from Gale and Co 15, Bouverie-street London E C and probably from other wholesale druggists

(3), and (4), the uncertainty of the views held by various observers on these points being ably shown by Dr. Fortescue-Brickdale. My observations were really confined to the question of boiling as a preventive measure against souring, and in this connexion I can only reiterate the assertions I made to Mr. Bevan—viz., that it is a very dangerous process if it be carried out for the purpose of *preserving* milk during those portions of the year when the prevailing temperature throughout the whole 24 hours does not fall below 65° F. The boiling of milk destroys the ordinary lactic acid organisms but it does not destroy the spore-bearing organisms that are almost invariably present, with the consequent result that when the milk is cooled and allowed to stand at a temperature in the neighbourhood of 70° F. a secondary fermentation takes place due to the development of these latter organisms. Herein lies the danger, for the milk does not sour but usually remains sweet in taste, though a very slight bitterness (due to the peptonising action of these bacteria) may perhaps be detected The temptation to use milk in this condition is naturally great, for apparently it is still in a sound condition, while, as a matter of fact, it is becoming rapidly charged with deleterious bacterial products. Now the development of these peptonising bacteria is in a clean milk almost completely checked by the wave of lactic acid fermentation, while if this be stopped by the process of boiling a perfectly free field is left to the sporogenous types to grow unhindered and to bring about a toxic condition of the milk which would otherwise not have occurred. If milk be boiled to be drunk immediately it may be, and probably is, as a preventive measure of the greatest value, but if the milk is going to be kept over night for consumption next day such an end is completely defeated. It may well be asked, "What, then, is to be done in the circumstances?" If I were to dare to suggest the word "preservative" harsher words than "iconoclast" might be used, but the question whether preserved milk or putrefying milk is the better as an article of diet I will leave others to answer, and although the addition of preservatives by the milk trade should on no account be allowed the addition of them in the home, under a medical man's direction with regard to quantity, is quite another matter.

I am, Sirs, yours faithfully,
CECIL REVIS.

King-street West, Hammersmith, W., Sept. 13th, 1904.

MATHEMATICS AND EXAMINATIONS IN PUBLIC HEALTH.

To the Editors of THE LANCET.

SIRS,—Medical officers of health in their annual reports have to submit figures of the increase and decrease of populations and to make calculations as to the death-rate, infantile mortality, birth-rate, &c., of their districts, and it is unfortunate that at the various examinations in public health candidates are not systematically tested on these points. They are often asked questions more likely to crop up in an insurance office, but the use of logarithms and the estimation of a population after the method of the Registrar-General are seldom asked for by the examiners. Surely these are practical matters which everyone who holds a diploma in public health should be acquainted with, but I have known cases where medical officers of health, fully qualified, were unable to make these calculations.

I am, Sirs, yours faithfully,
MU.

ST. BARTHOLOMEW'S HOSPITAL.—A history of St. Bartholomew's Hospital has been written by Dr. Norman Moore and will be published shortly by Messrs. C. Arthur Pearson, Limited. The work will be illustrated by original sketches by Mr. Howard Penton. The volume will be issued at two prices—namely, two guineas and one guinea—and the whole of the proceeds of the book will be given to the fund for the rebuilding of the hospital. A list of the subscribers to the first edition, which will be limited to 2000 copies, will be printed as an appendix to the work. Intending subscribers are requested to send their names to the honorary secretary of the rebuilding fund, St. Bartholomew's Hospital, Smithfield, London. This work should prove entertaining and instructive to many and a desirable acquisition as a work of reference to the student of history and philanthropy.

THE FEEDING OF SCHOOL CHILDREN.

HISTORY AND ORGANISATION OF THE PARIS CANTINES SCOLAIRES.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE supposed physical degeneration of the race has been the subject of so many sensational dissertations that public interest is now fully aroused and the nation is anxious to deal with the matter. It may be, as some very good authorities contend, that with a falling death-rate and a longer average duration of life it cannot be maintained that the race as a whole is losing its strength and vitality. On the other hand, no one has attempted to deny that there is physical degeneration among certain sections or classes of the community. Such degeneration must occur notably among those who in their infancy and childhood have been insufficiently or injudiciously fed. As, further, the law renders education obligatory we have in the primary schools a machinery all ready made and at hand permitting full investigation into the facts of the case. There are here also the means of remedying the evil wherever it shall have been proved to exist. Whatever political economists and others may say, no medical man would maintain that it is possible to educate an underfed child without grave risk to his or her health. From the physical point of view there can be no question but that the child must be fed first and educated afterwards. Nevertheless, it has been asserted over and over again that in London alone there are daily some 50,000 children who go to school without breakfast. Whatever the basis of this assertion and even if exaggerated there is not the slightest doubt that many of the children who attend the primary schools are often injudiciously fed, sometimes insufficiently fed, and on some days not fed at all. To attempt to teach children thus suffering is to waste public money as well as to injure the child pupils. It is certainly a means of producing physical degeneration. By law and by taxation schools and teachers are provided and yet food is more necessary than either school or teacher. This, of course, will be admitted by everybody. Only it will be said that parents ought to feed their own children. It is, however, the obvious fact that some parents either cannot or will not feed their children and this accounts for much of the physical degeneration. Nevertheless, years have rolled by and nothing has been done of a systematic character. Here and there charitably inclined people have organised soup kitchens in connexion with schools in very poor quarters, but these are sporadic local efforts and are not to be relied upon. Also it is not charity, with its pauperising and degrading influence, that is needed, but a national scheme by which, in some way or other, every child shall receive, without imposing any humiliating condition, all that is necessary for its physical as well as its intellectual development. How this is to be done and who is to pay the cost are problems that will not be easily settled. But it can be done, it has been done, and what has been achieved in other countries will probably be attempted here. In any case, if a foreign nation feeds all its children adequately and if all are not fed in England then, in time, we shall stand at a disadvantage when compared with that foreign nation. Now, the nation in question is our nearest neighbour, France. Surely it behoves us to know what has been done so near at hand and to see if this example may not serve as an object lesson.

It was from the school fund (*caisse des écoles*) that the school canteens (*cantines scolaires*) gradually merged into existence. In the latter days of the Second Empire a law on primary instruction was enacted which bears the date of April 10th, 1867. Article 15 of this law is thus worded :—

> A deliberation of the municipal council approved by the prefect may create in all communes a school fund for the purpose of encouraging [illegible] rewards to the most assiduous pupils and [illegible]e revenues of the school fund will consist [illegible] of subventions given by the commune, by the department, or by the State. With the authorisation of the prefect it may receive gifts and legacies. Several communes may be authorised to join together for the formation and management of such a fund. The service of collecting for the fund is rendered gratuitously.

M. Duruy, at that time Minister of Public Instruction, issued a circular on, May 12th, 1867, explaining this law. He said it was best to leave to the inhabitants the care of taking the initiative in the creation of such funds and drew attention to a fund already in existence in the Second Arrondissement of Paris This fund had been established by the National Guard in 1849, under the Second Republic The circular also calls attention to the fact that such funds are in existence in Switzerland where, "in accordance with a touching custom, newly married couples on their wedding day hand over to the school fund a sort of offering to childhood" The above law however, can only be qualified as the promulgation of an idea and the approval of a scheme, it did not enforce its application Three years later the Franco German war broke out and it was only three years after the war that the nation had sufficiently recovered from its disasters to think of these proposed reforms Early in 1874 a school fund was created at Montmartre, a district which has some 200,000 inhabitants, and in other localities This was done in harmony with the stipulation of the law of April 10th, 1867, but already in the minds of the more ardent friends of education the scope of the law was enlarged Thus the school fund of the Montmartre district so far back as 1874 issued a pamphlet in which the following passage occurs —

[illegible]

Thus, from the very beginning the idea germinated of giving material help in regard to physical requirements Very little, it is true, was done at first The distribution of strong thick boots is one of the first items on record Then there is also an account remaining of outfits provided for some young girls who had so distinguished themselves as to be admitted to the Ecole Normale or training school for teachers, but were too poor to dress themselves well enough to go to such an institution These and many other voluntary efforts made in different parts of France though altogether insufficient, had a double advantage They created the nucleus of future administrative bodies and prepared or ripened public opinion so that it was ultimately possible to convert into an obligation that which had formerly been but a voluntary effort This final step was brought about by the law of March 28th 1882 on compulsory education Article XVII of this law enacts that

> The school fund instituted by Article XV of the Law of April 10th 1867 shall be established in all the communes.

Thus every district is now compelled to institute a school fund and soon there followed a great change in the policy or the purport of these school funds Originally they were intended to aid the cause of education by urging children to attend school and by giving them prizes when they distinguished themselves Now the law compels everyone to go to school and also provides efficient teaching Therefore the school fund administration need not attend any longer to such matters but find ample occupation in seeing to the physical requirements of the pupils The police compel the children to go to school and the State by the appointment of teachers, attends to their education To the school fund remains the questions of food, of clothing and of health restoring holidays All these are matters of great complexity and [illegible] children to the country it may still be said that more might with advantage be attempted But if in this there remains room for further improvement it may now be said with confidence that in Paris and in most other places every child attending school receives a *wholesome* and a sufficient meal Personally I can only speak of what I have seen in Paris, but the law applies equally to the whole of France though the success of its application must depend to a large extent on the devotion or intelligence of each local school fund committee of control

That the question of health predominated in the management of these funds is shown by the preference very generally given to school colonies over school excursions, where there was not money enough for both By school excursion is meant an expedition of one or more days into the country The teachers, in accompanying the pupils, give such explanations of what is seen as to constitute object lessons This is at once a pleasant change and a useful means of education But it is generally considered far more beneficent and useful to select a certain number of sickly and debilitated children and to send them for several weeks to some bracing country place where their health may be thoroughly restored This is called a school colony and constitutes a great and happy feature of the educational machinery Thus, for instance, the Montmartre School Fund has purchased a magnificent mansion and its surrounding park at Luzancy, not many miles from Paris There four batches of 186 children spend several joyful weeks during the course of the summer living nearly all the time in the open air The school fund of the neighbouring district, the XVII Arrondissement, sent last year 137 children to the seaside at Fecamp and 281 to the country at Montlhéry, making in all 418 children who spent a total of 8500 days right away from the big town enjoying wholesome recreation in the fields or on the seashore What this means in health and happiness to these poor children cannot be expressed by mere statistics, it is best left to the imagination To help to defray the cost of these school colonies the municipality has voted an annual subvention of £8020 divided between the 20 school funds of the 20 Paris districts, or *arrondissements*, in proportion to the number of poor in each locality

As a rule, each school fund has three committees—one for the school canteens one for the provision of shoes and clothing and the third attends to the holiday excursions and holiday colonies The general committee from which these subcommittees are chosen generally consists of the mayor, the members of the municipal council, and the government school inspector of the district Then the voluntary subscribers to the fund elect out of their own ranks and by a ballot vote probably 20 or 24 committee men Thus the local authority and the local subscribers are both represented and share in common the task and responsibility involved Early in the day it was found expedient to obtain the assistance of ladies At first many of them were connected with church charities and were called lady patronesses But this did not work at all No one wanted to be patronised and the main object of education as at present organised being to inculcate the sense of the duties and of the dignity of the citizen any idea of charity is absolutely antagonistic to the whole spirit of modern educational reform The lady patronesses were no longer allowed to interfere and in their stead lady delegates were appointed Their mission is not to patronise but to see that the rules are applied and that everyone obtains his rights These ladies have a card bearing the stamp and signature of the mayor and also sometimes wear a ribbon favour of the colours of the town The lady delegates to the canteens must visit the schools under their charge at least once a week They inscribe the accounts on the printed formulas and see that all is absolutely clean and that the meals are well prepared In this respect the ladies have rendered great service, for it is due to their special knowledge and skill that the cost of the meals has been considerably reduced

It was in May, 1877 that the Prefect of the Seine informed the various school funds of Paris that the municipal council had determined to study how a good, wholesome, warm meal might be given to all the children once a day The answers at first obtained were not encouraging The school funds had not the means either in regard to management or in regard to their financial resources to attempt so vast an enterprise It was also estimated that such meals would cost on an average 25 centimes (2½*d*) each For the moment the matter dropped But in February, 1881, the question was raised whether all the children who were attending school and whose parents were in receipt of poor relief might not be given a meal while at school The school fund of the Montmartre district at once volunteered to undertake this service Other districts followed the example The municipality voted funds in aid, and a report presented for the year 1884–85 showed that during the year 15 canteens had served 1,110 827 portions, one third of these were helpings of soup another third meat, and the rest vegetables The children had paid 36 776 francs 90 centimes for 736 526 of these helpings, while 374,301 helpings had been given without payment The total cost was 59 264 francs 95 centimes The portion of meat then given weighed from 15 to 20 grammes and cost the school funds 0 0578 franc But soon and with better organised surveillance and management the portion was increased to 20 or 25 grammes and the cost was lowered to 0 045 franc

The system of feeding the children was thus fairly launched. It has now become universal and experience has taught that the cost need not be more than 15 centimes or 1½*d.* per meal of soup, meat, and vegetable. The latter naturally is a separate course, a substantial dish, properly cooked, not a little greenstuff boiled in water as we too often see in England. The principle now adopted is to encourage all the children, whether poor or not, to eat their meals together. A child may bring his own food with him from home but it is never so cheap and is always cold and rarely so good as the meal provided by the canteen. Therefore both children and parents prefer the canteen dinner, but the children who are not content with water bring their own wine or beer in bottles. Even the poorest children generally manage to mix a little wine with their water, particularly now that recent legislation in favour of hygienic drinks has reduced the retail cost of wine to 2*d.* per bottle and even less. From the very first the greatest care has been taken not to allow any loss of dignity to arise from the free feeding. The fundamental principle of the whole management is the absolute innocence of the children. They cannot be expected to pay. Their parents may be at fault; if so, there is only the greater reason to shelter the children and to try to preserve in them that sense of self-respect which might so easily be wrecked by their parents' bad conduct. Each child is called upon to pay 1½*d.* per day for his meal and receives in exchange a check or ticket. Sometimes this payment is effected in a small office, one child entering at a time. All receive a ticket for their dinner and only the person who gives the ticket knows who have paid and who have not. The parents of those who do not pay are visited. A full inquiry is made as to their condition and if they are poor they are put on the free list.

Of course it is easy to see that such a system might lead to much abuse. If the father is at work and has only one or two children the gratuity is refused. It is never refused to widows or workers with large families. To this I objected that the father, though earning high wages, might squander them in dissipation and starve his family. Was it not encouraging vice to feed his children? Or, again, others were clever in shamming poverty and to feed their children encouraged their hypocrisy and their lying propensities. All these and many other objections were met with the one simple, all dominating reply: "The children must be fed." There were methods of investigation; pressure was brought to bear on the parents. The parents or guardians of every child fed gratuitously were called upon and full investigations were made. Friends and witnesses and their employers were also seen when necessary. There was no objection to the show of some severity towards unworthy parents but the child was held sacred. In no case was the child to be humiliated or troubled in any way and on no pretext whatsoever should the food he needed be refused. Besides, there were various categories of gratuity. Persons who could not afford the 1½*d.* saved their dignity by paying a 1*d.* or only a ½*d.* per day. Nevertheless, in the poor quarters it is in the majority of cases of no use insisting on payment. The children arrive at 8.30 A.M. However poor their parents they generally have had something to eat before starting. Nevertheless there are some extreme cases of poverty, and then a piece of bread is given at the school when the starving child arrives. But this is altogether exceptional. It is at 11.30 A.M. that the mid-day warm meal is given. The children leave school at 4 P.M. and then they are supposed to dine with their parents in the evening. But to many of them it is the mid-day French breakfast that they get at school which constitutes their only satisfactory meal. A few children, however, cannot go home at 4 P.M. as their parents are out working. These are allowed to remain on the school premises till 7 P.M. where they play and prepare their lessons. Then they are given what is called a *goûté*, a sort of "snack," a little bread and butter or jam. Such is the full scope of the feeding undertaken by the school funds though all that is outside the 15 centimes midday meal is exceptional. How far the feeding is gratuitous varies according to the district. At the Eppinette district only 20 per cent. of the children pay for their meals. At Batignolles the proportion is 40 per cent. and in the wealthiest quarters of Paris as many as from 60 to 70 per cent. of the school children pay for their midday repast. The school funds, in so far as they depend on voluntary contributions, could not feed all these children and during the last three years the Paris municipal council has given to the various school funds of the capital subventions amounting to £40,000.

Such is the general principle on which the system works. Each locality manages its own affairs and is assisted by subventions from the centre and there is emulation between the various funds. It is now only necessary to add a few words as to the canteens themselves. They are object lessons in cleanliness and in simple but refined cooking. The meat is weighed after it has been cooked, the bone and fat being removed; then the younger children get 20 grammes and the older children 30 grammes of cooked meat. The *menu* is, generally speaking, somewhat as follows. Three days a week there is *bouillon gras*, a delicacy unknown in England, as no ordinary English person will take the trouble to put the proper proportion of flavouring herbs and vegetables to the beef. Only twice a week is the boiled beef with which the soup has been made given for the second course. As this meat is lighter than roast meat care is taken to supply for the third course the most substantial vegetables—namely, lentils or haricot beans. What a difference it would make if in England the people knew how to cook these highly nutritious vegetables. At one of the canteens I watched and inquired as to the process. First some onions are fried in good grease, in preference the melted fat of pork or veal. Then some thyme and some laurel leaves are added with "just a suspicion" of garlic. The haricot beans or lentils that have been soaking in water all night are placed over this savoury sauce. Its fat counteracts their dryness and the aroma of the herbs, onions, and garlic confers an appetising flavour. On three days a week roast beef, pork, veal, or mutton is given, preceded by a tasty vegetable soup and followed by a dish of mashed potatoes, or of maccaroni cheese, or of rice and milk, all well flavoured, well cooked, and of excellent quality. Such is the three-halfpenny meal of three courses provided alike to the poor and the well-to-do children attending the primary schools of Paris. But this is not all. The medical officers who examine the children may prescribe larger portions where necessary and quite a number of weakly children have cod-liver oil given to them in winter and syrup of iodide of iron or phosphate of lime in summer.

If the cooking is refined some attempt is also made to refine the manners of the children. So as not to dirty their clothes they are taught to use serviettes, and, generally speaking, the masters or mistresses pay their 1½*d.* and take their midday meal with the children, eating exactly the same thing. This example gives confidence and does much good. It is also a very effective way of controlling the cooking. Thus we have the hopeful spectacle of what in England would be pauper children sitting side by side with other children who are in much better circumstances and eating simple but refined food at the same table as gentlemen or lady teachers who have won their university degrees. Then, so that the poorer children should not be looked down upon, care is taken not only to conceal the fact that they are unable to pay for the meal but out of the school fund simple articles of clothing are given them. These poor children do not, therefore, look shabby and thus their self-respect is maintained. Is there not in all this the making of a healthy people and a strong race? Can we in England afford to ignore the example here given? Is it not safe to argue, as the managers of the school funds in Paris argue, that whatever the faults of the parents, whatever may be done to the parents, still the children are blameless? Therefore, and without hesitation, if we would preserve the race, without the loss of a moment and without making a single exception, every hungry child must be fed. Economists, politicians, and others were left to discuss and to squabble over the rights and wrongs of the case, the school funds of Paris, encouraged by the municipality, commenced by building the kitchens, cooking the meals, and somehow or other things fell into their places, and to-day everyone is quite content and some not a little proud of the good that has been done.

WIGAN MEDICAL SOCIETY.—A meeting of this society was held on Sept. 1st, Mr. J. Chronnell, the President, being in the chair. There was a good attendance of members. A vote of condolence was passed to Lady Banks and her son in their recent bereavement. The honorary secretary (Mr. W. Berry) read a paper on Death Certification. An interesting discussion followed.

LUNATICS IN WORKHOUSES

(FROM A CORRESPONDENT)

IN an article entitled "The Muddle of the Law of Lunacy" which appeared in THE LANCET of Feb 27th, 1904, p 612, attention was drawn to the difficulties which surround the admission of persons of unsound mind into a workhouse as a preliminary to their examination by a magistrate Assuming that these difficulties have been in some way evaded it may prove that the form of mental defect exhibited by the patient is one which the law regards as capable of being suitably dealt with in the workhouse itself, and it may, therefore, be not without profit to consider what are the conditions under which persons may be so detained for care and treatment

The lunatics who become more or less permanent occupants of workhouses are, in the [illegible]
mental disability takes the
elderly dements, and (3) [illegible]
of age. All these may reach the workhouse either directly from the outside world or by transfer from an asylum for acute cases under Sections 25 and 26 of the Lunacy Act, 1890 This latter group does not usually cause much trouble as the procedure required by the Act is fairly simple, but the construction of Section 24 of the Act, which controls the detention of cases of the former kind, has provided innumerable themes for discussion Subsections (3), (4), and (5) of Section 24 are the ones with which we are here chiefly concerned and it is proposed to indicate some points of interest which the attempt to apply them has brought out Several opinions given by the Commissioners in Lunacy, which have not previously been made public, will be incidentally referred to As will be seen from a perusal of Subsection (4) two medical certificates are required One of these is in the familiar form numbered 8 in the Schedule to the Act and may be given by any legally qualified medical practitioner, provided that he is not a medical officer of the workhouse concerned, while the other must be by the medical offic
state (1) that the person wh
lunatic, (2) that he is of a
workhouse, and (3) that there
and suitable accommodation for the lunatic This second certificate, which is in the form numbered 10 in the Schedule to the Act, differs also from the former one in that it has no place for the "facts communicated by others" of form 8 These certificates accompany and "support" the application for a detention order which is made to "a justice having jurisdiction in the place where the workhouse is situate" and their chronological relation to each other and to the application is worth a moment's consideration In a case recently submitted to the Commissioners in Lunacy for their opinion the justice had made an order for detention which was dated 16 days after the date of the medical certificates This order the Commissioners declared to be invalid and they directed that the medical officer of the workhouse in which the patient was being detained should take steps to obtain a new order from a justice The limit of time between the giving of the certificate by the medical officer of the workhouse and the making of the order by the justice is 14 days, exclusive of the day on which the certificate was given This may be assumed from the fact that the certificate upon which the justice proceeds is in the same form as the one by means of which the medical officer, acting under Section 24 (2), is enabled on his own responsibility to detain the lunatic for 14 days In the opinion of the Commissioners the order in which the medical certificates are given is of no consequence, the order in which they are mentioned in Section 24 (4) and referred to above being apparently merely accidental This matter was brought before the notice of the Commissioners in May last in some cases where the outside practitioner had certified first, and they replied that they did not think "that the fact of the certificate, given by the medical officer of the workhouse under the provisions of Section 24 (2) of the Lunacy Act, 1890, being dated after the date of the certificate given by the outside medical practitioner would cause an order made upon these two certificates to be invalid" There is, however, a serious objection to such an arrangement which medical men who may be invited to give certificates would do well to bear in mind, and it is to be found in the fact that whereas the certificate given by the *workhouse* medical officer is alone sufficient authority for detaining the patient for not more than 14 days, that *given* by the *outside practitioner* has by itself no such effect It would indeed appear that in the cases alluded to the patients were illegally detained in the workhouse for several days and, if any of them had known the circumstances and had been of a litigious disposition, as paupers frequently are, they might have caused those concerned a considerable amount of trouble

The words "not being an officer of the workhouse," as applied in Section 24 (4) and (5) to the outside practitioner, have been prolific in disputes As they stand the words do not necessarily exclude all the medical officers of the union or parish to which the workhouse belongs, thus it seems legitimate for a district medical officer to certify in conjunction with the workhouse medical officer and to receive payment for so doing In London, especially, the position is complicated by the fact that the sick wards of the workhouse may be aggregated into a distinct institution, the "workhouse infirmary," which may be situated at a distance from the workhouse proper and may have a separate medical officer Accommodation for lunatics may be provided either at the workhouse or at the infirmary and the medical officer of the establishment selected is, for the purposes of the Lunacy Act, the "medical officer of the workhouse" The question then arises whether the medical officer of the branch where the lunatics are not confined is competent to give the certificate required from a "medical practitioner not being an officer of the workhouse" A recent
ows, will serve
the infirmary,
[illegible] on adjoining
plots of land and the medical officer of the workhouse was also medical superintendent of the infirmary. Acting in his

practitioner It was attempted to justify this proceeding by the contention that the assistant at the infirmary occasionally took duty for his senior at the workhouse and that it has been held that a workhouse medical officer's deputy may properly give certificates as an outside practitioner under Section 2. is,
indeed, to be found in [illegible]
of lunacy, but it is to b [illegible] a
case decided in a court of law but on an opinion given, in reply to a correspondent, in the *Justice of the Peace* for April, 1891 More important still, it has no bearing on the point at issue since the deputy in question is one appointed by the medical officer in accordance with Article 199 of the General Order of the Local Government Board, Dec 8th, 1847, and Article 200 of the General Consolidated Order of July 24th, 1847, and such a deputy is not an officer of the workhouse or of the guardians An appeal was made to the Commissioners in Lunacy and they held that in this instance, at any rate, the infirmary was part of the workhouse and that "the assistant medical officer referred to could not sign the certificate in question under the hand of a medical practitioner not being an officer of the workhouse" In connexion with this branch of the subject it may also be noted that there appears to be no reason why in suitable cases one medical officer's certificate should not refer to several patients provided these are properly distinguished and enumerated The question as to whether or not it is permissible for a guardian who is a member of the medical profession to sign the certificate of the outside practitioner and receive pay for so doing has been recently raised Such an arrangement appears open to criticism In a note in Glen's Poor law Orders under Article 177 of the General Consolidated Orders, dated July 24th, 1847, which deals with certain payments for special medical services, the opinion is expressed that "as a general rule it is thought not desirable that a medical man who is a guardian of the union should give certificates under this Article in his own union" and this principle appears to be one which the Local Government Board would approve The view of the Commissioners in Lunacy is set forth in the reply to a communication which in June last was made to them in regard to a case where a guardian had given a medical certificate in support of the application for a detention order It is to the effect that "a member of a board of guardians is not an officer of the workhouse within the meaning of

Section 24 (4) of the Lunacy Act, 1890." One must infer, therefore, that an order for detention obtained in such circumstances is valid.

Section 24 (5) deals with the question of the fees payable for medical certificates. "The guardians of the union to which the workhouse belongs shall pay such reasonable remuneration as they think fit to the medical practitioner who, not being an officer of the workhouse, examines a person for the purpose of a certificate under this section." No fee, that is, goes to the workhouse medical officer. This circumstance has afforded material for numerous speculations which it would be idle to go into; the medical officer may adopt whichever affords him *the most consolation*. But even for the outside practitioner there are pitfalls. A medical man was recently asked by a relieving officer of one of the great London unions to certify as to the mental condition of certain patients whom it was proposed to detain under Section 24. No stipulation was made as to the fee to be charged and a sum of one guinea for each of the half dozen cases was demanded. The guardians, however, declined to pay more than three guineas on the ground that the decision as to the amount rested solely with them and in this instance their action was not contested. Perhaps for this reason they have since been endeavouring to get the certificates at 5*s*. It is probable that the guardians' powers under the section are not so extensive as they suppose. In April, 1902, the issue was raised in an action brought in the Chertsey county court before his honour Judge Lushington. A claim for seven guineas was made for certifying seven imbeciles at the Chertsey workhouse and the guardians refused to pay more than three. The medical man therefore sued the guardians for the full amount and it was contended on his behalf, and admitted by the opposing counsel, that the word "reasonable" in the section only determined the question as between the guardians and the Local Government Board in respect of a possible surcharge. The fee of one guinea was shown to be a customary one and judgment was given for the plaintiff for the amount claimed with costs on the higher scale. There seems to be no very good reason why the fee payable should not have been fixed by the justice who makes the order for detention, even though the cases falling under Section 24 differ from those in which summary reception orders are made, in that the justice does not himself call in the medical practitioner who certifies.

The machinery of Section 24 is usually set in motion by a relieving officer who, according to Subsection (4), *may* make application for a detention order. From the use of the word "may" it is to be inferred that if circumstances rendered such a course convenient the medical officer or the master of the workhouse might take the initiative. It is worth noting also that under this section the application need not be in writing, and, further, that it is not necessary for the justice who makes the detention order to see the patient in respect of whom it is made. Section 5 of the Lunacy Act, 1891, requires that the medical certificates, given under Section 24 of the Act of 1890, should be attached to the order and the certificates should be laid before the Commissioners in Lunacy on the occasion of their next visit to the workhouse.

In London the care of "lunatics in workhouses" devolves largely upon the Metropolitan Asylums Board. The institutions for lunatics controlled by that body are not, however, "asylums" within the meaning of the Lunacy Act, 1890. That Act indeed specifically includes the asylums of the Board under the term "workhouses" (cf. Section 341), and in so far as the Act applies to them the detention of lunatics is effected through the agency of Section 24 as at other workhouses. The Lunacy Acts, however, do not constitute the sole controlling authority, there are numerous orders of the Local Government Board which have to be complied with. In consequence of this the procedure laid down for obtaining the admission of patients to these asylums is decidedly complicated as compared with that followed when persons are removed to county and borough asylums and calls for the preparation of the documents enumerated below when the lunatic is over 16 years of age.

1. Application by a relieving officer to a justice having jurisdiction in the place where the workhouse is situate for an order for the detention of the lunatic in the workhouse of the parish or union to which he is chargeable.
2. Statement of particulars by the relieving officer to accompany the application.
3. Certificate by the medical officer of the workhouse under Section 24 of the Lunacy Act, 1890.
4. Certificate by an outside medical practitioner under the same section.
5. Order for detention made by the justice under the same section.
6. Order for the admission of the patient to one of the asylums of the Metropolitan Asylums Board signed by the clerk to the guardians of the parish or union from which the patient proceeds. At the present time the Board's asylum at Tooting Bec is the only one which directly admits patients of the class here referred to.
7. Certificate by a medical officer of the parish or union to which the patient is chargeable to the effect that the patient is "a chronic and harmless lunatic, idiot, or imbecile" suitable and physically fit for removal. This certificate differs in several respects from the certificate referred to in paragraph 3 *supra* though its general purport is the same and it is usually given by the same medical officer. The chief difference seems to be that it may include "facts communicated by others."
8. A report "signed by the chairman or vice-chairman of the board of guardians of the parish or union to which the pauper is chargeable or by some member of the visiting committee of such board of guardians."
9. A second medical certificate as to the patient's bodily condition is frequently advisable for the following reasons. The admission order mentioned in paragraph 6 *supra* is, according to the Order of the Local Government Board of Feb. 10th, 1875, which regulates admissions to the asylums here considered, to be signed by the clerk by direction of the board of guardians, and it is further laid down that "such direction shall not be given until the certificate and report above mentioned (cf. 7 and 8 *supra*) have been laid before the board of guardians." The medical certificate must therefore be anterior in date to the admission order and as this is available for seven days it sometimes happens that the statement of the medical officer as to the patient's physical fitness for removal has been made so long before the removal to the asylum actually takes place as to afford no satisfactory evidence about the patient's condition at that time.

The detention order mentioned in paragraph 5 *supra* directs the detention of the patient in the workhouse in regard to which the medical officer has certified that there is suitable accommodation and would not, on the face of it, be a valid authority for detaining the patient in one of the asylums of the Metropolitan Asylums Board. This difficulty is, however, met by Section 4 (2) of the Lunacy Act of 1891 which directs that no further certificate or order shall be required "upon the transfer from a workhouse to an asylum provided under the Metropolitan Poor Act, 1867, of a lunatic, with regard to whom a certificate or order under the said Section 24 [i.e., of the Lunacy Act, 1890] made while he was in the workhouse is in force." It may be noted here that the medical certificate mentioned in paragraph 7 *supra* is required for the admission, not for the detention, of the patient and is therefore not excluded by the Act of 1891, however superfluous it may, on its own merits, appear. In connexion with paragraph 1 *supra* should be read Section 24 (7) of the Lunacy Act, 1890, which enables an officer of the asylum to act as a relieving officer in matters relating to paupers in the asylum.

A modification of the above procedure is adopted in the case of children under 16 years of age. No order for detention is obtained from a justice, apparently on the ground that in these instances the interests of all concerned are sufficiently safeguarded by the principle that the detention of a lunatic is justifiable at common law if necessary for his safety or the safety of others. The force of the objection raised in paragraph 9 *supra*, to having the medical certificate as to fitness for removal given several days before such removal, is recognised in this instance by the Local Government Board which, by an Order dated May 5th, 1890, requires that the certificate should be given on the day of the removal or on the day immediately preceding. As the admission order in these cases is available for 14 days both the certificates, numbered 7 and 9 above, will be usually required. When the child reaches the age of 16 years an order for detention under Section 24 of the Act of 1890 is obtained, but there is here a slight departure from the course prescribed in the Act, since by Section 4 (2) of the Lunacy Act, 1891, the medical superintendent is not required to certify that the asylum has sufficient accommodation for the proper care and treatment of the case.

Patients may be transferred to one of the asylums of the Metropolitan Asylums Board, as to a workhouse, under

Section 25 of the Act of 1890 and the Local Government Board, by an Order dated Jan 30th, 1891 made special provision for the admission of such cases This consisted chiefly in dispensing with the certificate and report alluded to above in paragraphs 7 and 8 *No provision, however* seems to be made for dealing with such cases of chronic insanity as are referred to in Section 26 of the Act of 1890 as suitable for detention in a workhouse

IRELAND

(FROM OUR OWN CORRESPONDENTS)

Milk in Dublin

AT a meeting of the board of guardians of the South Dublin Union held on Sept 7th a motion was adopted with reference to the great increase of infant mortality in Dublin due to the adulteration of milk and other causes Sir Charles Cameron and Professor E J McWeeney have stated that the milk from the town dairies is better and more trustworthy than that brought in from small farms in the country As to the infantile mortality of the city, the chief medical officer of health said that it was 150 per 1000 of the population, being below the average of the largest 76 English towns but higher than that of London On being asked to suggest a remedy he expressed the opinion that the whole of the supervision of dairies and cowsheds should be under the veterinary department of the State which would employ a staff of veterinary inspectors to examine the condition *of the cows and the hygienic conditions under which they* were kept Professor McWeeney, when asked as to the means for obtaining pure milk for young children said that the law might be modified so that establishments might not be registered as dairies unless they complied with certain conditions as regards ventilation air space, and cleanliness At present anyone who wished to sell milk could have his premises registered He was in favour of licensing rather than registering, stringent conditions to be imposed on licensees as regards the state of their premises cowsheds byres &c , and especially in respect to the arrangements for scalding their milk vessels In respect to a suitable method of adjudging punishment to those who sell under the title "milk ' a watered skimmed, or separated substitute Sir Charles Cameron is not in favour of imprisonment or of denouncing the convicted dairy proprietor by placing a placard over his door, for magistrates have generally much difficulty in such cases in bringing home the guilt to any individual What he proposes is shortly as follows The Act defines the legal standard of milk—namely, that it must contain 8½ per cent of non fatty solids and 3 per cent of fats Such legalised milk is poor and he would advise prosecution in all cases in which such milk was sold with punishment, no matter what excuse was made by the dairy proprietor On the other hand the 'average ' standard is 9 per cent of non fatty
and punishment should not
shown by the defendant tha
standard from poor feeding of the cows, while it was still as it came from the cow and unadulterated Under the present law no prosecution can take place until the milk is found by the analyst to be under the legal standard, although it may possibly be watered or lowered much below the average standard of good milk

A Fine Old Poor law Medical Officer

The grievances of the Poor law medical officers of Ireland do not always shorten their lives Dr Thomas Woods of Parsonstown has been the medical attendant at the fever hospital and dispensary of Parsonstown union for 40 years He is close on 90 years of age a clever man, an ardent cyclist, with his faculties entirely unimpaired The largest pension under the Poor law was voted to him the other day and it was well deserved, for, as was stated by Mr Michael Reddy, M P , J P , during all his years of service no complaint was ever made against him There seems a sort of bathos in the chairman's announcement that the amount of his pension will be slightly over £200 per annum for both his appointments

Queen s College, Belfast

For the chair of pathology in Queen s College, Belfast which was endowed by a Belfast merchant the late Sir James Musgrave, Bart , and which is now vacant, the medical profession in Ulster are strongly in favour of the appointment of Dr Thomas Houston who has for the past seven years devoted himself specially to the subject and has been an assistant of the professor who has just resigned As *an indication of the local feeling it is stated that a memorial* is to be presented to the president of Queen s College which
dical staff of all the Belfast
of Dr Houston and his former
in his favour Dr Houston was
a most distinguished student of the Belfast Medical School, in which he is now a lecturer

The Belfast Board of Guardians

The Local Government Board has approved of the proposal of the Belfast guardians to acquire the premises known as the Abbey, Whiteabbey, with a view of converting them into an additional workhouse and it has written saying that it will await the further action of the guardians in the matter When a letter to this effect was read at a meeting of the board of guardians on Sept 6th it led to a wild scene There seems to be great opposition to the scheme on the part of some of the guardians

Anti vaccinationists

The Local Government Board has written to the Belfast *guardians commanding them to* enforce the Vaccination Act in the union As a result one of the guardians, a working-man candidate for Parliamentary honours, is to be prosecuted for non compliance with the Act

Health of Belfast

Between July 17th and August 20th 202 cases of zymotic *disease were notified in* Belfast including 51 of typhoid fever 60 of simple continued fever, 49 of scarlet fever, 27 of erysipelas eight of diphtheria, two each of typhus fever small pox and puerperal fever, and one of membranous croup The small pox epidemic is dying out there have been since the outbreak of the disease 105 patients treated in the small pox hospital, of whom 98 have been discharged convalescent three have died, and four remain in hospital 344 persons were isolated as 'contacts " and there are still nine The death rate was 17 2 per 1000 In reference to the sanatorium for consumptives it was reported at a meeting of the council on Sept 6th that a conference was to be held between a subcommittee of the public health committee and some members of the Forster Green Consumption Hospital board of management the idea being that this hospital should be taken over and developed by the corporation to prevent overlapping

Small pox and Typhoid Fever in Armagh

There are 27 cases of small pox in the isolation sheds and three cases of typhoid fever in the fever hospital at Armagh

Treatment of Consumption in Londonderry

The visiting committee of the guardians of the Londonderry union has recommended that a shed should be erected in the yard attached to the infirmary for the treatment of consumptive patients at a cost of £10, but at the weekly meeting of the guardians on Sept 10th it was decided by a vote of 12 to 6, not to do anything one excuse being the expense !

Sept 13th

PARIS

(FROM OUR OWN CORRESPONDENT)

The Overcrowding of the Medical Profession

LAST week I gave your readers some account of the overcrowding of the medical profession, but bad as it is it is no worse now than in former years, for instance according to an annual for the year 1825 there were in Paris 716 *doctors in medicine*, 30 *officiers de santé*, and 165 surgeons —in all 911—for a population of 717 212 To-day the population is 3 000 000—that is to say, four times as great—and the proportional number of medical men therefore ought to be four times more—namely, 3644 It is, however, not so big, for, as a matter of fact, there are in Paris at the present time only 3427 physicians and surgeons, but, on *the other hand*, the relative increase in the numbers of *pharmaciens* is very much greater In 1825 these numbered 252, which number should be, in proportion to the population, 1000 in 1904 but really the number is 1290 The class which has most increased since 1825 is that which includes midwives and dentists. In 1825 there were 26 midwives and 55 dentists. In 1904 there are 988 midwives and 638 dentists.

Instruction in Tropical Medicine.

There are at the present time in France three institutes of colonial medicine which were founded in the following order: the first at Marseilles, the second at Bordeaux, and the third at Paris. The course of instruction at the last-named covers about two and a half months and the session of 1904 will commence on Oct. 17th and will finish about Christmas. Theoretical instruction and laboratory demonstrations are given at the Faculty of Medicine and clinical instruction at the Hospital of Auteuil. Theoretical instruction and laboratory demonstrations take place every weekday afternoon except Mondays at the practical school. Clinical instruction is given twice a week at 10 o'clock in the morning at the Auteuil Hospital. During the first year of its existence the Paris school had 20 students and during the second year there were 25, of whom 13 were foreigners. The Ministerial Decree dated 1901 approved a resolution of the University Council of Bordeaux that a diploma in colonial medicine of this University should be granted. The municipality and the Chamber of Commerce of Bordeaux both contributed to the expenses of this diploma. During the last period of instruction at Bordeaux, which began on Nov. 16th, 1903, and finished on Jan. 30th, 1904, there were 24 students, of whom 15 who were not sufficiently instructed or had not yet taken their diplomas of doctor in medicine did not go up for the examinations. Nine students, of whom one was a foreigner, obtained the diploma in colonial medicine of the University of Bordeaux. The coming term of instruction will begin next November and will finish in February, 1905. The only question now remaining is as to what occupation shall be found for the young medical men who are sent out from these institutes of colonial medicine. If possible something should be done to assure the diplomates of colonial schools that without infringing the legitimate rights of the military medical men attached to the colonial troops they should be found places as medical officers to consulates or medical officers of civil establishments in the colonies. Certain commercial companies throughout the colonies engage medical men at very fair salaries. At the last colonial congress a motion was passed to be submitted to the Government authorities that medical men might be given administrative functions in the French colonies, but no answer has been returned to this resolution.

Cryoscopy of Milk.

At the meeting of the Academy of Sciences which was held on August 29th M. Guiraud and M. Lasserre communicated the results of some researches which they had recently made upon the state of health of a milk-giving mammal as to the freezing point of milk. The freezing point of pure milk taken at the farm is constant and lies between $-0{\cdot}5°$ and $-0{\cdot}6°$ C. The artificial addition of water always gave results which were in a constant ratio. The state of health of the animal providing the milk has a definite influence upon the freezing point. All milks having a pathological origin, particularly the milk of tuberculous cows, showed a freezing point which was very sensibly lower than that of normal milk.

The International Congress of Tuberculosis.

At this Congress, which will meet in Paris from Oct. 2nd to 7th, 1905, three subjects in each section will be discussed. Three members of the Congress are appointed to open the discussion on each question and one of them must be French. The national foreign committees are already nominating who shall represent them and the French ones have already been appointed. The Pathological Section, of which the president is Professor Lannelongue, has chosen the three following questions: (1) Treatment of Lupus by New Methods, to be opened on behalf of France by M. Jeanselme and M. Chatin; (2) the Early Diagnosis of Tuberculosis by New Methods, to be opened on behalf of France by M. Achat; and (3) the Comparative Study of Tuberculous Diseases, to be opened on behalf of France by Professor Arloing of Lyons. The Social Section, which will be presided over by Professor Landouzy, will discuss the following: (1) the Etiological Factors of Tuberculosis, the opener of the discussion on behalf of France being M. Romme; (2) the Part played by Dispensaries and Sanatoriums in the Fight against Tuberculosis, to be opened on behalf of France by M. Courtois-Suffit; and (3) Insurance against Tuberculosis, to be opened by M. Edouard Fuster.

Fees paid to a Medical Man for Treatment at a Hospital.

The Juge de Paix of the canton of Redon has just delivered an interesting judgment. A doctor of medicine demanded that M. X., a builder, should be compelled to pay him 250 francs for medical attendance which he had given to a workman who was injured while in the employ of M. X. The court condemned M. X. to pay the medical man the sum demanded—that is to say, 250 francs—on the ground that medical men attached to hospitals are not compelled to give gratuitous attendance to hospital patients unless they are admitted as indigent persons and that it cannot be said that workmen who meet with accidents during their employment are to be classed as indigents. The court also found that the sum of 250 francs was by no means too high.

Sept. 13th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Death of Professor Kobner.

Professor Heinrich Köbner, who died in Berlin on Sept. 3rd, was one of the leading specialists on diseases of the skin in Germany. He was born in 1838 at Breslau where he received his medical education and took the degree of M.D. in 1860. He first became an assistant at the Breslau Physiological Institution under the celebrated Professor Heidenhain and afterwards, according to the custom of the time, went to Vienna and Paris where he began to study skin diseases. In Vienna as well as in Paris this special branch of medicine was already receiving attention and instruction could be obtained from competent teachers, whereas in Prussia there was no educational centre except Berlin where dermatology could be properly studied, because diseases of the skin formed an extra subject in the medical or surgical clinics respectively and on that account were rather neglected. When in 1862 Professor Köbner settled in Breslau he opened a private clinic for diseases of the skin where the first courses and lectures in dermatology in Germany were held. In 1869 he was recognised as *privat-docent* and in 1872 was promoted to be extraordinary professor. In 1876 an official dermatological clinic was established by the university and Professor Köbner was appointed director but unfortunately the state of his health soon afterwards compelled him to leave Breslau and to pass some time in a southern climate. Eventually he settled in Berlin where he resided till his death. While studying in Paris he was specially interested in sycosis and his subsequent original work included researches on this disease, on lepra, on psoriasis, on tuberculosis of the skin, and on new growths affecting the skin. His extensive knowledge not only of his own special branch but also of almost every branch of medicine obtained for him one of the largest consulting practices in Berlin and he was celebrated for the accuracy of his diagnosis, even in the most obscure cases. Two years ago he retired from practice on account of failing health but he occasionally attended the meetings of the Dermatological Society, of which he was the founder.

The Title of Professor.

A singular question relative to medical titles has recently arisen in Hamburg. This free city (and the two other free cities, Bremen and Lübeck, likewise) are the only States of the German Empire where honorific titles are rare and the manifold titular distinctions possessed by Government officials and prominent citizens in the other German States do not exist either in medical or in any other circles. Hamburg, which has no sovereign ruler (the Emperor is not to be regarded as sovereign of the German States with the exception of Prussia) but is governed by its Senate, has hitherto abstained from the use of titles and decorations which are of so great an importance throughout the rest of Germany; even men like the celebrated Dr. Kümmel, the chief surgeon to the great Eppendorf Hospital, have only the title of Doctor like any general practitioner of the city of Hamburg. There is no medical councillor or privy medical councillor or sanitary councillor or any similar appellation. A medical man is termed a "doctor" and when he has a government appointment he may be called "medical officer to the port" or "district medical officer of health" or "chief physician to the hospital' but has no honorary title at all This state of things, so natural to English people, is evidently a matter of grievance to some leading Hamburg medical men who may possibly feel uncomfortable when they meet their professional brethren of the other German States who are provided with titles A combination of them, including hospital physicians and surgeons, specialists, and others, have therefore petitioned the Senate that the title of Professor may be granted to those who deliver lectures They draw attention to the fact that regular courses of post graduate lectures, though not of an official character have been delivered in Hamburg for many years They say that post graduate study, as in Prussia, should be recognised by the State and that Hamburg by its excellent hospitals and other medical institutions may become the seat of a medical school like Cologne The teachers of the prospective school and meanwhile those of the unofficial post graduate lectures should have the title of Professor granted to them which, as they explain, is the usual title in Germany for medical men engaged in academical teaching The demands of the above combination have, however, led to a protest on behalf of the medical profession, the majority of whom do not wish the old customs of Hamburg to be abandoned and are, moreover, afraid that the titled medical men may be regarded by the public as more competent than others This question has caused some discussion from both sides in the medical and lay press but the Senate has not yet decided the matter

NEW YORK

(FROM OUR OWN CORRESPONDENT)

Mosquitoes in New Jersey

FOR the past two years strong efforts have been made by the health authorities of New Jersey to banish, or at least to decrease the number of mosquitoes in that State Unfortunately, endeavours in this direction have not been attended with a large measure of success Drainage has been the measure most widely relied upon but it would seem that the scheme has failed probably because it was not conducted in a sufficiently thorough manner In Newark, New Jersey, for instance a city partly surrounded by marshes, the sum of $4500 had been appropriated to carry out a system of draining The result has been very disappointing for the ditching, instead of draining off the water, has converted the swamp into a huge pond and matters, so far as mosquitoes are concerned, have been worse than ever before Mosquitoes in the vicinity of Newark have been prevalent during the present summer and from all parts of New Jersey comes a similar story The truth undoubtedly is that only partial measures have been adopted, whereas if mosquitoes are to be got rid of in a district a thorough system of drainage must be undertaken Of course, the expense will be heavy but the results will be commensurate with the money expended

Medical Exhibits at the World's Fair

The medical exhibits at the World's Fair are many and varied With the exception of those of the Marine Hospital Service and of the Medical Department of the Army and Navy, in the Government Building, they are all in the [illegible] exhibit is on the whole [illegible] to the medical sciences [illegible] most interesting features of this exhibit is the section given over to the exhibition of the Roentgen rays Six sections contain the main exhibition of the medical department, in each section one branch of the medical sciences being represented The surgical exhibit is arranged in two sections, one of which represents the Royal Surgical Clinic of Berlin and the other the Royal Surgical Clinic of Breslau A room adjoining the surgical section is devoted to the pathological exhibit A section is also set apart for the exhibit of internal medicine The entire German exhibition of medical sciences is remarkable for the thorough manner in which it has been conceived and carried out and reflects great credit upon those responsible for its arrangement

Medical Men and Politics in the United States

The question of medical men and politics is greatly exercising the minds of the profession in the United States As is generally the opinion in England, it is thought here by a large number of medical men that the practitioner should take no part in politics However, a change is apparent as regards this point of view and many influential medical men are now insisting that they should share in politics both for their own sakes and in the interests of the public at large The argument is advanced that in a great many ways the medical man is peculiarly well fitted to take part in politics He is educated, well read, and has especially good opportunities of judging human nature and is generally in a position to speak with authority on certain matters It is not argued that he should take so much an active part in politics as to influence votes Upon questions of public health and upon all matters concerning the health of the community as well as upon purely medical questions he is better adapted than members of any other class to pass an authoritative opinion In fact, much sickness might be avoided if the advice of medical men were asked and acted upon by municipalities and the Government It is further contended that the entrance of medical men into politics would tend to raise the tone of political life and to decrease the corruption so prevalent in politics nowadays The American Medical Association at its recent meeting at Atlantic City took cognisance of the matter and several of its more prominent members urged strongly that medical men should interest themselves in politics The vice president of the association indeed advocated the formation of a national department of health, represented by a physician at its head, who should be a member of the Cabinet

Typhoid Fever in the Borough of the Bronx

In that part of greater New York known as the Bronx a somewhat serious epidemic of typhoid fever has broken out A reservoir is being constructed there, working upon which are a large number of Italian labourers, and it is among these that the disease originated The Italians in New York are a constant menace to the public health owing to the insanitary conditions in which they live They herd together like cattle and have not the slightest rudiments of proper sanitation Fear is expressed that the present epidemic of typhoid fever in the Bronx may lead to a contamination of the water supply and attention is again drawn to the fact that there is no efficient system of filtration of the public water supply of New York Indeed, New York is one of the few large cities of the world that have not adopted modern filtration as a precautionary measure against water infection, although such methods have been urged times without number To state the case plainly, the metropolis of the United States, a large proportion of the inhabitants of which are dependent on a water shed badly protected, is content to run risks which can be easily obviated by modern science Physicians as a rule do not care to press the matter On occasions the medical journals will utter warnings The *New York Medical Record* has done so frequently The great stumbling block, however, to the carrying out of an efficient system of water filtration is the large primary cost For this reason all municipal administrations have fought shy of the matter

Death of Dr William R Pryor

Dr William R Pryor one of the best known physicians of New York city and professor of gynæcology in the New York Polyclinic Hospital since 1884, died on August 27th from pneumonia Dr Pryor, who was only 43 years of age, was considered among the best of the gynæcologists of America He was the son of Supreme Court Justice Roger A Pryor The deceased probably owed his death to his devotion to duty, as in addition to a large practice he gave much of his time to work amongst the poor

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

Bubonic Plague

A case of bubonic plague, the tenth since the beginning of the present outbreak, was reported in Sydney on August 3rd Three of these ten cases have proved fatal The staffs of men employed by the Board of Health and Sydney city council continue a persistent crusade against rats and still find infected rats among those destroyed No fresh cases have been reported from the other States

Sunderland. A number of gentlemen are also vice-presidents without a seat on the council unless specially elected.

Medico-Psychological Association of Great Britain and Ireland.—The next examination for the certificate in nursing and attending on the insane will be held on Monday, Nov. 7th. Candidates should obtain from the registrar, Dr. Alfred Miller, Hatton Asylum, Warwick, a schedule to be filled up, signed, and returned to him at least four weeks before the date fixed for the examination. Monday, Oct. 10th, will be the last day upon which, according to the rules, candidates can enter their names for the November examination.

Notes, Short Comments, and Answers to Correspondents.

CASTOR OIL IN ANCIENT EGYPT.

M. Loret, who for many years has devoted himself to the study of the plants known to the ancient Egyptians and their pharmacopœia, has recently in the *Revue de Médecine* been discussing the hieroglyphic name of ricinus and the application made of it by their medical men. He shows that the plant they knew was the African and Arabian variety and that they utilised it for the production of oil and other purposes centuries before the Indian type of ricinus was known to the Greeks. Herodotus tells us that the Egyptians derived the oil from it by boiling the grains, whilst Dioscorides and other *classic authors only attribute a cold process of extraction to them.* It was used for medical remedies and lighting and anointing. Herodotus and Diodorus call the oil of ricinus χιχι, whilst Pliny and Dioscorides assign that title, which seems an Egyptian word, to the *plant. M. Loret proves that the Egyptian name was Tekem,* which Brugsch considered to be the olive; it really consists of two words first noticed in a Den

M. Loret in his paper then pro

Tekem in the Ebers medical

for medical history will be mu

medical papyrus acquired for t

because it is a sort of duplicate of the Ebers manuscript, though the list of diseases and remedies follows a somewhat different order. The comparison of the two treatises will, it is hoped, be made by Baron Dr Oefele, whose competence for the task is great. M. *Urbain Bouriant, the French Egyptologist, who for the last few years* bestowed all his energy upon the translation and explanation of a Coptic medical papyrus discovered at Meshaikh and now preserved in the French Archæological Institute at Cairo, died last year at the early age of 54 years During his illness he still continued working at his edition of the papyrus, and M. Pierre Bouriant writes that his relative *has left him such complete* notes and wise counsels concerning the manuscript that he can finish the work for him and place it upon his tomb "comme un hommage d'amour et de vénération."

A NEW ONE-TWELFTH INCH OBJECTIVE.

WE have received for trial a one-twelfth inch oil immersion lens made by Mr. Henry Gowlland, Selsey, Chichester, the cost of which is only £2 15*s*. We have submitted the lens to a thorough trial and are able to report most favourably upon it The definition is good, it admits plenty of light and affords a satisfactory field. It has one defect that, we think, *might be remedied without difficulty.* The lower milled head is too projecting, consequently when removing the lens from the microscope the adjustment of the constituent lenses is apt to be disturbed. We can recommend the lens as a thoroughly good one, although it can be obtained at a low price.

HOSPITALS AND DISPENSARIES.

To the Editors of THE LANCET.

SIRS,—About this time last year you were kind enough to give admission to a letter in which I made the suggestion that an alliance between the hospitals and the dispensaries (provident, charitable and semi-charitable, &c.) presented certain advantages. By this alliance the dispensaries would be *the primary public portals* to the hospitals, except in cases of accident, urgency, and perhaps those cases sent up by medical men The advantages which such a scheme presents are 1 Stoppage of leakage of hospital funds in *directions inexpedient and inappropriate. 2 Stoppage of the fearful* waste of time, injurious both to the public and *to the hospitals,* in the present overcrowded condition of the casualty and out patient departments. 3. Prevention of the pauperising effect of the present free and unchecked system of medical relief, with corresponding increase of thrift and self-dependence 4 Enhanced means of study by students of those complaints often somewhat cursorily *regarded as of slight* importance but which experience has shown to constitute the bulk of cases in actual practice. 5. Extended scope for remunerative occupation of newly qualified medical men. 6. The scheme could be carried out without any appeal for funds. These ends would be *attained* by placing the dispensaries freely open to students of the hospital to which they were affiliated and encouraging them to assist in the work there carried on. The dispensaries from their more accurate local knowledge would act as invaluable filters, their independent position enabling them to exercise discretion as to the distribution of hospital relief.

The cases would there be sorted, those fitted for the dispensary or casualty treatment retained, the more complex or serious passed on to the *hospital either for admission to the wards or for more recondite* treatment than would be available at a dispensary, into the special and out-patient departments, and so on. Experience even of the present working of these dispensaries shows clearly that after a short period for adjustment to altered circumstances they would certainly be self supporting and possibly a source of income. There would be a "provident" side attached to each such affiliated dispensary and a small charge made to all applicants not subscribing to the provident fund. Such arrangement would tend to prevent loss of self-respect in the applicant. There is practically a very small proportion of the populace which would be unable to meet this charge and such as were or are so would surely be fitting cases for the Poor-law. Of course, such a scheme requires a considerable amount of detailed working out and a letter like this is not the place in which such details can be explained. But I think that many, if not all, will see that some such plan would go far to meet the difficulties under which we at present labour and that methods are conceivable by which the idea of combining the hospitals and dispensaries and thus securing the above advantages could be worked out.

One such method I foreshadowed in my former letter, but I am quite prepared to find that many of its details might be improved to the advantage of the ultimate arrangement of the scheme. If there be one fact which study of this question of hospital abuse through a period of 20 years has rendered clear—at least to me—it is that the remedy *must be found in outside action*. The evil can never be checked by the hospitals themselves. Here, then, is a suggested means to the end desired. I venture to ask you, Sirs, once more to extend your indulgence to me in this matter.

I am, Sirs, yours faithfully,

Stamford-street, Sept. 12th, 1904. W. HENRY KESTEVEN.

A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—I beg to state that the paragraph in which my name was mentioned in the press was inserted absolutely without my knowledge.

I am, Sirs, yours faithfully,

ELLA SCARLETT-SYNGE, L.S.A., M.D. Brux.

THE CLIMATIC TREATMENT OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—Could you advise me in your next issue what part of Switzerland would best suit a delicate girl with incipient phthisis?

I am, Sirs, yours faithfully,

ept. 5th, 1904. RUSTICUS.

*** Perhaps Davos or St. Moritz might be suitable.—ED. L.

THE PASSAGE OF FOREIGN BODIES THROUGH THE INTESTINE.

To the Editors of THE LANCET.

SIRS,—I remember two peculiar cases of passage of foreign bodies through the intestinal canal that occurred in my practice. A child was brought to me and when asked of what she was complaining I got the reply that she had swallowed her dolly; and I found it to be true, for next day she passed a little china doll an inch long. In another case, when the patient was asked what was the matter, I received the remarkable answer that she had swallowed a copper tea-kettle. This also proved to be true, for a day or two afterwards a beautifully made little copper tea-kettle was brought to me with spout and handle complete that her father had made out of a penny. No pains or ill-effects occurred in either case.

I am, Sirs, yours faithfully,

S. T. HUGGINS, L R C.P. Edin., M.R.C.S., Eng.

Compton-terrace, N., Sept. 9th, 1904.

To the Editors of THE LANCET.

SIRS,—*Re* the passage of foreign bodies through the intestines the three following cases may prove interesting. 1. A child, aged six years, swallowed a piece of broken glass, triangular in shape, its sides measuring, roughly, seven-sixteenths of an inch each, its depth being three-sixteenths of an inch. 19 hours afterwards the body was passed per rectum with little discomfort and very slight hæmorrhage. 2. A man, aged 30 years, swallowed a penny and for 16 hours he felt a certain amount of uneasiness; he then "lost it" and at the end of four days and 11 hours passed it per rectum without any trouble. 3. A child, aged four years, swallowed a halfpenny and though no urgent symptoms arose for two days he then began to vomit incessantly. An application of the x rays showed the coin in the œsophagus. The coin-catcher happened to push it on into the stomach and 22 hours after entering the stomach (four days and four and a half hours after it was actually swallowed) the halfpenny was passed per rectum after an enema, the first action of the bowels since the accident.

I am, Sirs, yours faithfully,

Sept. 11th, 1904. CHAS. J. GIRLING.

THYROID GLAND IN THE TREATMENT OF CANCER.

To the Editors of THE LANCET.

SIRS,—I shall be greatly obliged if any members of the profession would let me know through the medium of THE LANCET their experience of the administration of thyroid gland in the treatment of cancer. Dr. Robert Bell has given his views in a very pronounced way in a pamphlet he has lately written. I am, Sirs, yours faithfully,

Sept. 12th, 1904. M.D.

◆

Mr. E. Peacock.—Our correspondent's attention is directed to an interesting article upon red light in the treatment of small-pox by Dr. T. F. Ricketts and Dr. J. B. Byles which appeared in THE LANCET of July 30th and the continuation of which appears in this number of THE LANCET. Dr. Finsen has also tried the treatment and has published articles thereon. Our correspondent is doubtless aware that the method was mentioned in the thirteenth century by Gilbertus Anglicus who stigmatised it as an old woman's fable and in the next century by John of Gaddesden who reported that he cured a member of the Royal family by wrapping him up in scarlet cloth.

County Coroner.—The black cockade is the badge of the royal house of Hanover worn by the servants of those who are in the service of the Crown. Coroners are now appointed and paid by county councils to perform local services; it may be, however, that they are still servants of the King and acting under his authority. We believe that strictly speaking only those who hold (or have held and are specifically allowed to retain their privileges on retiring) commissions in His Majesty's Navy and Army are entitled to the use of cockades.

Xylol.—The University of Liverpool came into existence as a university in 1903. Previously to that the medical school was at University College. The following are the numbers of medical students who entered for the full course from 1899: 1899-1900, 52; 1901-02, 50; 1902-03, 34; 1903-04, 111. This last figure was quoted to us by the dean of the University but was, we believe, subsequently corrected. We cannot at present put our hand on the modified figure.

Yellow Fever.—We should think, though we have not the book at hand to refer to, that "A Monograph of the Culicidæ or Mosquitoes," by F. V. Theobald, printed by order of the trustees of the British Museum, would give our correspondent the information which he requires. Three volumes of this monograph have been printed and the last one was reviewed in THE LANCET of June 25th, 1904, p. 1798.

Inquirer.—The points raised by our correspondent are purely legal. Assuming breach of the contract without good cause he would be entitled to damages, the measure of which would be subject to the opinion of the judge as to the length of notice which the terms of the contract might be considered to imply. So far as custom goes we believe three months' notice to be usual.

F. G. B.—There is, so far as we know, no redress for people who put themselves into the hands of quacks except by an action for obtaining money under false pretences and even then it is extremely difficult to prove in a court of law that the quack promised anything in particular.

Asthma.—The effect of climate on an asthmatic patient is so variable that it is very difficult to lay down any definite rules. For our correspondent's son we should suggest Bournemouth or St. Mary Church in England and Hyères or Cimiez abroad.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index to Vol I of 1904, which was completed with the issue of June 25th, and the Title page to the Volume, were given in THE LANCET of July 2nd

VOLUMES AND CASES

VOLUMES for the first half of the year 1904 are now ready Bound in cloth gilt lettered, price 18*s* carriage extra

Cases for binding the half year's numbers are also ready Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand W C are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates on this or on any other ground, should be resisted The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

During the week marked copies of the following newspapers have been received—*Hertfordshire Mercury Liverpool Daily Post Yorkshire Post Forfar Herald, Leamington Spa Courier Scottish Reformer, Surrey Advertiser, Beverley Recorder Manchester Evening Chronicle &c.*

Communications, Letters, &c., have been received from—

A.—Dr. Henry Ashby, Manchester; Mr. T. M. Allison, Newcastle-on-Tyne; Aston Union, Clerk of; Messrs. Allen and Hanburys, Lond.; Ancoats Hospital, Manchester, Secretary of.

B.—Mr. P. V. Bhatt, Jamnagar; Messrs. Barnett and Shirer, Lond.; Mr. R. Brereton, Mountrath; Messrs. N. Barriasson and Co., Cognac; Messrs. J. Brown and Co., Singapore; Messrs. Burroughs, Wellcome, and Co., Lond.; Brin's Oxygen Co., Lond., Secretary of; Messrs. Barton Bros., Brighton; Dr. N. D. Bardswell, Mundesley; Mr. P. Stanley Blaker, Lond.; Mr. William Berry, Wigan; Dr. Thomas Buzzard, Lond.; Dr. J. Brunton Blaikie, Lond.; Sir W. H. Bennett, Lond.; Messrs. J. Beal and Son, Brighton; Dr. T. R. Bradshaw, Cwm-y-glo; Mr. W. G. Burcombe, Lincoln; Mr. J. G. Bisset, Aberdeen.

C.—Mr. A. W. S. Curties, Wakefield; Central London Throat and Ear Hospital, Secretary of; Corporation of Manchester, Medical Officer of Health of; Cortland Wagon Co., Lond.; Dr. Harry Campbell, Lond.; Cotswold Sanatorium, Cheltenham.

D.—Dr. E. J. Day, Dorchester; Captain S. R. Douglas, I.M.S.; Duryea Co., Coventry; Dr. P. J. Daly, Cork.

E.—Mr. J. D. Eames, Leeds.

F.—Sir Ernest Flower, Lond.; F. G. B.; Major G. H. Fink, I.M.S., Lond.; Mr. Charles W. Fielding, Ongar.

G.—Messrs. W. Gaymer and Son, Attleborough; Messrs. Garland, Smith, and Co., Lond.

H.—Sir C. Holman, Aldeburgh; Mr. J. Heywood, Manchester; Horton Infirmary, Banbury, Assistant Secretary of; Hull Royal Infirmary, Secretary of; Mr. David Hunter, Edinburgh; Dr. R. W. Haslett, Pontypool; Miss Mary C. Horne, Devizes.

I.—Messrs. Ingram and Royle, Lond.

J.—J. A. B.

K.—Mr. B. T. King, Lond.; Kidderminster Infirmary, Secretary of; Dr. C. F. Knight, Edinburgh; Messrs. R. A. Knight and Co., Lond.

L.—Dr. J. D. Leigh, Bishop Auckland; Dr. H. Gwynne Lawrence, Chepstow; L. E. E.; Messrs. Lee and Martin, Birmingham; Leith Hospital, Secretary of.

M.—Mr. J. McMurtrie, Glasgow; Medical Society of Victoria, Melbourne, Hon. Treasurer of; Maltine Manufacturing Co., Lond.; Mr. N. T. Methley, Portbury; Manchester Children's Hospital, Secretary of; Midland Counties Asylum, Birmingham, Secretary of; Messrs. Moss and Co., Lond.; Dr. A. W. Miller, Lond.; Dr. Charles Mackey, Pendlebury; Mr. L. F. Simeon Maberly, Clifton; Mr. L. Macdonald, Helmsdale; Mr. E. Moore, Castleisland.

N.—Newcastle-on-Tyne Corporation, Clerk of; Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.

P.—Mr. F. Piggott, Cambridge; Preston Royal Infirmary, Secretary of; Dr. T. F. Pedley, Rangoon; Messrs. Parke, Davis, and Co., Lond.; Dr. G. Steele Perkins, Lond.; Messrs. Peacock and Hadley, Lond.; Pool's Advertising Offices, Lond.

R.—Mr. Ernest Ringrose, Newark; Reuter's Telegram Co., Lond.; Mr. Charles Roberts, Tunbridge Wells; Revenant; Mr. G. A. Roberts, Wolverhampton; Roosevelt Hospital, New York, Superintendent of; Messrs. Reynolds and Branson, Leeds; Mr. C. C. Rushton, Macclesfield.

S.—Mr. F. H. Simmons, Johannesburg; Messrs. S. Smith and Son, Lond.; St. John's Hospital for Diseases of the Skin, Lond., Secretary of; Saarbach's News Exchange, Mainz; Storthes Hall Asylum, Kirkburton, Clerk of; Messrs. Scott Brothers, Lond.; Dr. John F. Strickland, Halifax; Mr. Robert Stopford, Auckland; "Sanitas" Company, Lond., Secretary of; Miss E. Synge, Lond.; Mr. B. F. Smallman, Lond.; Dr. J. A. Shaw-Mackenzie, Lond.; Scholastic, Clerical, &c., Association, Lond.

T.—Dr. John H. Tonking, Camborne; Mr. J. Thin, Edinburgh; Mr. Percival Turner, Lond.; Mr. W. Tylar, Birmingham.

V.—Mr. G. Viner, Perranporth; Mr. F. C. W. Vogel, Leipzig.

W.—Dr. W. Wingrave, Lond.; Wincycle Trading Co., Lond.; Messrs. A. J. Wilson and Co., Lond.; Messrs. J. Woolley, Sons, and Co., Manchester; Professor A. E. Wright, Lond.; Mr. A. Willbond, Lond.; Messrs. John Wiley and Sons, New York; Mr. H. A. Wanklyn, Lond.; Mr. H. B. Wilkinson, Ivybridge; Messrs. H. Wilson and Son, Lond.

Y.—Dr. Eric E. Young, Lond.; Major M. T. Yarr, R.A.M.C., Bombay; Yellow fever.

Z.—Messrs. A. and M. Zimmermann, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. J. L. Allen, Colchester; A. F. C.; A. L.; A. B.; A. C. S.; Dr. J. H. Abram, Liverpool; A. W. T.; A. E. G.; A. R. H.; A. A. B.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

An Address

ON

ARTERIAL SCLEROSIS,

ESPECIALLY IN REGARD TO ARTERIAL HYPERMYOTROPHY AND THE OTHER MORBID CHANGES WHICH OCCUR IN THE MUSCULAR TUNIC OF THE ARTERIES.[1]

Delivered before the Pathological Society of London on Feb. 16th, 1904,

BY THOMAS D. SAVILL, M.D. LOND.,

PHYSICIAN TO THE WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM; PHYSICIAN TO THE ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, LEICESTER SQUARE.

MR. PRESIDENT AND GENTLEMEN,—These investigations were initiated at the Paddington Infirmary where, during the seven years I was medical superintendent, nearly 500 necropsies were made on persons 60 years of age and upwards, many of whom presented circulatory symptoms during life and some of them died from the semi-invalidism we call old age. The inquiry has been continued, as far as my leisure and eyesight would permit, during the last ten years, making 17 years in all. The opportunity has thus been afforded me to examine not only the visceral arterioles but to pay more attention than is usually devoted to arteries of all sizes and in all positions throughout the body.

Definitions.—I was accustomed to define arterial sclerosis, in my own mind, as a chronic generalised thickening, condensation, or degeneration of the arterial walls, in which, after death, the lumen does not collapse as usual, and the walls are harder and less elastic than normal. Histologically such a condition may occur in three situations—in the tunica media, when it may be properly termed medial sclerosis; in the tunica intima, when it might be called intimal sclerosis; or in the tunica adventitia, when it might be termed adventitial sclerosis. Such a division of chronic [illegible] ase is more [illegible] of chronic [illegible], and peri[illegible] respectively, each being in some degree clinically and pathologically separable from the other and each being of very different relative importance. In regard to atheroma (a patchy fibroplastic infiltration of the intima) those who make many necropsies on the bodies of the aged can, I think, have very little doubt that atheroma and intimal sclerosis (the generalised thickening just referred to) are two totally distinct pathological conditions (Table I.), as Dr. William Russell[2] and others have already pointed out. Atheroma is apt to be confused histologically with the obliterative endarteritis of syphilitic and other origin which occurs for the most part in younger subjects, but it ought not to be confused with intimal sclerosis which is more generalised. Some atheroma can always be found in the bodies of persons aged 60 years and upwards who may have died without circulatory symptoms or accidents of any kind, as in the woman aged 100 years, to whom I shall refer directly, and the conclusion has been forced upon me that atheroma is of no serious pathological importance provided the cardio-vascular system is otherwise fairly healthy. The evil results sometimes attributed to atheroma—in the brain, for instance—can very often be accounted for by the yielding of the vessel wall *between* the patches and the kinking of the artery which ensues.

TABLE I.—*Showing the Distinction between—*

Atheroma.	Intimal Sclerosis.
Patchy localised fibroplastic infiltration of intima prone to undergo necrotic changes.	Fibrous thickening of the intima ent re with little, if any, tendency to necrosis.
Raised *yellow* spots or patches located on one side of an artery. These can be felt as beaded thickenings during life when the superficial arteries are affected.	Not a raised patch but a more or less uniform thickening all round the lumen of an artery without alteration of colour. Affects a considerable length of a vessel which may give to it a smooth hard feel like whipcord, not a beaded thickening.
Affecting chiefly the aorta and the *larger* arteries of the trunk and brain. May be of very limited extent. Very often met with at *the bifurcation of vessels even* in quite healthy subjects.	May affect arteries of any size but relatively more common in the medium and smaller vessels, usually affecting a considerable *vascular area and often found* in association with arterial dilatation.

In regard to adventitial and intimal sclerosis I have met with many cases in which it could be legitimately inferred that chronic adventitial and intimal sclerosis of the larger and medium-sized arteries had been secondary both in time and importance to changes in the media or (as Thoma first pointed out) to dilatation of the arterial lumen. A distinction should, I think, be drawn between intimal sclerosis in the peripheral (microscopic) arterioles on the one hand and intimal sclerosis in the medium-sized and larger arteries on the other. Their causes appear to be distinct, and certainly their effects are, for the former may obstruct [illegible] from the inference sometimes drawn that because intimal sclerosis exists in the arterioles of the kidney it also exists in the other peripheral arterioles. This is by no means so in my experience and the kidney constitutes only a small portion of the whole peripheral circulation of which the voluntary muscular system constitutes a very large part, and it does not appear right that too much attention should be concentrated on the visceral arterioles, or on the microscopic arteries at the expense of those of larger size. In this paper I propose, however, to direct my attention chiefly to the morbid changes in the muscular tunic of the arteries and to deal, first, with the relative importance of the muscular coat; secondly, with the morbid changes met with in the muscular tunic; and, thirdly, with the pathological condition which I have previously described as arterial hypermyotrophy, *its causes, and its consequences.* The data on which these investigations have been based consist of cases under my care during life (often for several years) and examined after death at the Paddington Infirmary. Clinical and pathological details will be submitted of 29 cases (out of 257 necropsies in 19 months) in [illegible] ptoms or accidents without [illegible] explanation other than their [illegible] during life.

THE RELATIVE IMPORTANCE OF THE MUSCULAR COAT.

The muscular coat of the arteries is relatively to the other two tunics the most important histologically, physiologically, and pathologically. The muscular tissue forms the thickest tunic of all the arteries and arterioles of the body, only excepting arteries of quite the largest size in which very little muscular tissue is found. In the arteries and arterioles it forms about half the thickness of the vessel wall and constitutes the functionally active part of the entire arterial system. The intima is only a limiting membrane; the adventitia is only a supporting structure of connective tissue; but the media, by the exercise of its functions, controls the circulation as a whole as well as the quantity of blood in this or that area or organ. These muscular fibres form, in short, the parenchyma or proper tissue of the arterial system. But whereas imperfections in the parenchyma of other physiological systems only affect the functions of that particular organ, any imperfection of the muscular coat of the arteries affects directly or indirectly the nutrition and oxygenation of all the organs and tissues of the body and disturbs not only the equilibrium between the different systems but also that important equilibrium between the heart and arteries on which the perfect health and life of every individual depend. We also know, thanks to the observations of Dr. George Oliver and othe [illegible] of vital [illegible] but to th [illegible] positions [illegible] equilibrium of different parts of the peripheral circulation, and therefore it is not surprising to find that postural vertigo is among the most prominent symptoms when the muscular coat loses its elasticity, contractility, or regulator powers. The older authors regarded old age as a loss of

---

[1] Being the opening of a discussion on arterial sclerosis.

[2] THE LANCET, June 1st, 1901, p. 1519.

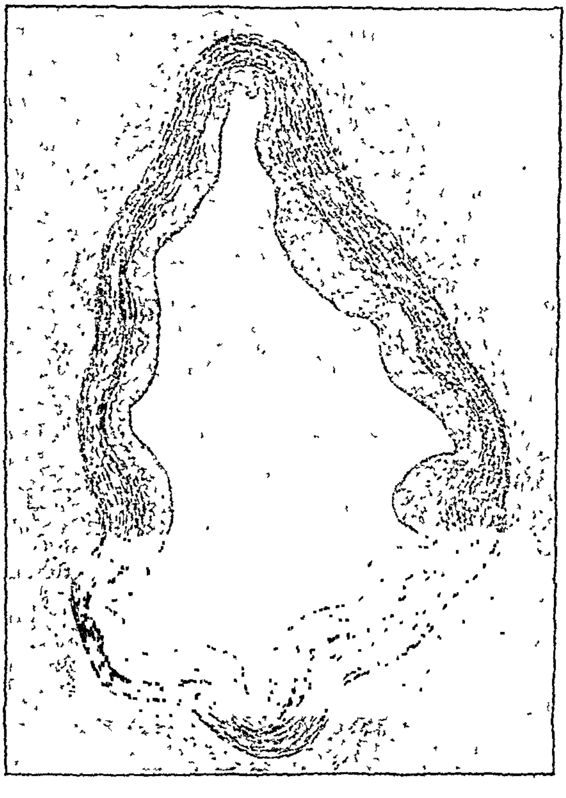
No. 4230.

balance of functions and this was probably true in regard to the equilibrium between heart and arteries. But the most important constituent of incipient old age, in my view, is the loss of the regulator function of the arteries.

Turning to the pathological aspect, we know that extensive valvular disease of the heart or of the endocardium may exist without inconvenience so long as the muscular wall is healthy and we also know that fat may be deposited outside the heart and fibrosis amounting even to obliteration of the pericardial cavity may exist without very seriously affecting its action as long as the muscular tissue is healthy. Similarly in my experience widespread atheroma or intimal sclerosis on the one hand, or a marked adventitial sclerosis or peri-arterial fibrosis on the other has existed in many cases without manifesting any clinical or pathological consequences *provided the tunica media be fairly healthy.* As one among many illustrations of these statements the following case may be mentioned, the case of a woman who died in the Paddington Infirmary at the age of 100 years in October, 1890. Her mental and bodily powers became very gradually weaker and she passed away with no definite evidences of active disease either before or after death excepting hypostatic congestion of the lungs and a certain degree of pulmonary fibrosis so commonly present in the bodies of aged persons, accompanied by a few spots of incipient broncho-pneumonia latent during life. She was under observation for many months and during life there was no history or evidence of any derangement of the circulatory system. After death the naked eye and microscopical examination (upwards of 50 sections of the arteries and organs were examined) revealed: 1. Widespread atheroma of the systemic and cerebral arteries reaching a degree that I have rarely seen. It was found not only in the larger vessels, where it is usual in persons over 60 years of age, but also in the medium-sized and smaller vessels throughout the body and even in the ultimate ramifications of those of the brain. In the arch of the aorta one or two atheromatous patches were breaking down into what are sometimes called atheromatous ulcers, but there had been no embolism, thrombosis, or vascular rupture of vessels in any part of the body or brain. 2. The lumen of all the arteries of the body was increased to one and a half and in some of the larger arteries—e.g., the common iliac—to two and a half times the normal size. 3. The heart was small, not hypertrophied or dilated, and microscopically, excepting for moderate periarterial fibrosis and the usual brown atrophy of old age, it was normal. Besides the patchy atheroma there was in this case (4) generalised intimal sclerosis (diffuse thickening of the intima) and (5) generalised condensation and thickening in the adventitia (adventitial sclerosis), both of which changes may, I believe, in this case be regarded as secondary to, and compensatory of, the arterial dilatation. But (6) *the muscular tunic of the arteries presented practically no change*, especially when we consider her age (Figs. 1 and 2). Some degree of granular changes existed in the lower extremities, but not more than I have met with in many persons of half her age. The thickness of the media was diminished but careful measurements showed it to be strictly in proportion to the dilatation which existed. (Specimens of the organs and the cardio-vascular system were exhibited at the meeting of the Pathological Society.)

FIG. 1.



Radial artery (stai[illegible] of a woman, aged 100 years, [illegible] *arteries of* this case, a perfe[illegible] the artery is dilated and the m[illegible] The artery also shows intimal and adventitial sclerosis, which, in this case, I regard as compensatory to the dilatation. This case exhibited extremely widespread atheroma but no circulatory complications at any time.

It is surprising what grave disease of the intima may exist without at any rate local consequences. Here, for instance, is the anterior tibial artery of a woman (Case 67[4]) who died at the age of 81 years from an intercurrent malady (epidemic skin disease). The lumen of the vessel was narrowed by an atheromatous patch undergoing necrosis to only one-tenth of the normal, yet no circulatory effects or accidents occurred in the limb.

These cases are only two of many that could be quoted as supporting the conclusions: (1) that extensive patchy atheroma and even generalised intimal and adventitial sclerosis are quite consistent with extreme longevity and with the total absence of circulatory *symptoms*, accidents or complications, provided, firstly, the tunica media be relatively free from hypertrophy or disease, and secondly, the balance between the heart and arteries is not disturbed; and (2) that [illegible] disease of the muscular tunic is a s[illegible]. A slight and hardly measurable increase in the muscular tunic, spread over the entire arterial system, must have a very considerable influence on the dynamics of the circulation and on the nutrition of the body generally. Arterial hypermyotrophy is, however, only a starting point to muscular degeneration in many cases.

MORBID CHANGES MET WITH IN THE MUSCULAR TUNIC.

Muscular tissue occurs in all but the very largest arteries. The changes I have met with in the muscular tunic (apart from lardaceous disease, which hardly comes within the scope of arterial sclerosis) are atrophy, hypertrophy, cloudiness, and granular degeneration (which are always more or less generalised throughout the arterial system), and necrosis and calcification (which are mostly localised and limited). The methods of revealing these are given in the schedule of cases submitted.[5]

1. True *atrophy* of the tunica media, that is to say apart from the thinning due to dilatation of the calibre of the arteries, I have only met with as an accidental condition. A slight degree of amyotrophy was sometimes found after death from prolonged wasting disorders. Thus atrophy was met with in three emaciated cases dying from chronic pulmonary tuberculosis out of four examined, in two cases of chronic pyelitis, and in one of scirrhus of the pylorus. The atrophy or thinning of the media appeared in all of these instances to be due to a wasting of the protoplasm of the muscular fibres as judged by the undue approximation of the neighbouring nuclei.

2. *Hypermyotrophy* (Figs. 3 and 4)—i.e., an increase in the number or volume of the muscular fibres of the arteries, resulting in an increased width of the media, with or without some of the other changes about to be mentioned, was of very frequent occurrence. The almost universal occurrence of a slight degree of hypertrophy in the bodies of persons past middle life led me at one time to infer that some degree of hypertrophy of the media might be normal in advancing years just as hypertrophy of the heart has been

---

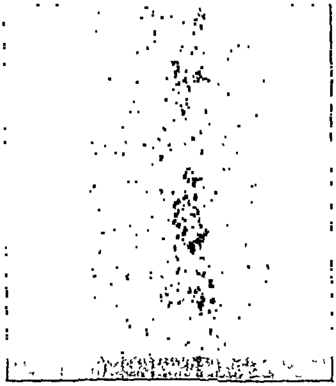
[4] These numbers refer to a schedule of cases published in the Transactions of the Pathological Society, 1904.

[5] Transactions of the Pathological Society of London, 1904.

shown to occur in the aged.[6] But the measurements are too refined and the conditions for which allowances have to be made, such as the size of the lumen of a vessel, are too [illegible] changes about to be mentioned. At any rate, in all the cases I have examined I have never met with nebular or granular degeneration or necrosis without some degree of the former (after allowing for the dilatation or contraction present) though hypermyotrophy was sometimes met without the degeneration. Hypermyotrophy and its other consequences will be referred to more particularly later.

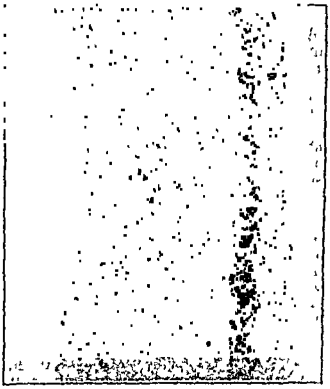
3. *Cloudy or nebular degeneration* of the muscular fibres (Fig. 3) consists of a faint cloudy condition of the protoplasm mostly accompanied by enlargement of the fibres. With logwood and other ordinary stains slighter degrees of this cloudiness are not revealed but with neutral orcein the faintest degree becomes manifest. When treated in this way the tunica media of the lower limbs of nearly all persons examined past middle life showed some slight cloudy changes. Cloudiness in the protoplasm apparently commences in the innermost layers of the tunica media, for it was always most marked in this situation.

FIG. 2.



Brachial [illegible] 00 years, the same patient [illegible] media for comparison [illegible] It also shows the intimal [illegible] to in the text.

FIG. 3.



Brachial artery (× 60) of a man, aged 73 years, showing arterial hypermyotrophy, with commencing granular degeneration in the inner layers and nebular changes in the outer layers of the media.

4. *Granular degeneration* (Fig. 3), like th[illegible] dominated in the inner layers of the t[illegible] occurred together with cloudy changes in [illegible] forms and is probably an advanced stage of [illegible] tunica media in granular degeneration is brittle and more difficult to mount, the muscular fibres lose their outline, their protoplasm breaks up into fine granules, and later the muscle nuclei also break up. This granular condition seems to me to correspond in some respects (its usual areas of distribution in the arterial system, for instance) with the "diffuse arterio-sclerosis" described by Thoma.[8]

Dilatation of an artery, local or general, was often associated with either of the two preceding changes, and with it there may be an *apparent* thinning of the media. Both the adventitia and intima of such dilated arteries were, in my experience, as in the case of the woman aged 100 years, almost invariably denser and thicker than normal, and this adventitial and intimal sclerosis should, I think, be regarded as compensatory and conservative conditions. Probably dilatation itself is in a sense a conservative process in cases of persistent high tension.

5. *Necrosis* of the media consists of local spots or foci of amorphous débris which take a very dark stain with aniline or logwood. The parts of the artery on each side of a focus may be quite healthy in some cases (e.g., Case 42) and such a focus is then very easily overlooked, while in other cases the media is also the seat of cloudy granular changes.

6. *Calcification* of the media was not so common as the preceding changes. It was met with in the later stages of arterial disease in two forms. Sometimes it was seen in the form of plates which had apparently succeeded the necrotic changes just referred to. These plates must not be confused with the more common atheromatous plates in the intima (particularly of the bigger vessels) which may encroach on, but do not originate within, the media—*a fact which can be revealed by the use of acid* orcein to define the boundaries of the tunics. A second variety of calcification takes the form of spicules surrounding the lumen of an artery which appear to be due to a transformation into calcareous material of swollen muscular fibres or bundles of fibres. These spicules were apt to be more generalised than the plates and might (as in a man aged 66 years) render entire lengths of various arteries as rigid as gas-pipes. Both necrosis and calcification are fairly common in the popliteal artery even when the rest of the arterial system is fairly healthy.

[illegible] may present a very striking resemblance to fibrous tissue both to the naked eye and under the microscope. But adequate preparation and staining have always brought out the characteristic rod-shaped nuclei of involuntary muscular tissue between the internal and external boundaries (as defined by acid orcein) of the tunica media. The media may of course be encroached on and apparently dilated and thinned by dense fibrous intima, as in the renal arterioles of some cases of chronic interstitial nephritis.

It is not possible to give statistics as to the relative frequency of these several changes because they were so commonly associated in varying degree in the same patient. Hypertrophy, cloudy changes, and granular degeneration of the media are undoubtedly generalised changes such as would arise from nutritional, dynamic (e.g., high tension), or toxæmic causes. They were always generalised in their distribution, though apt to predominate in some vascular area, very often in the arteries of the lower extremities—a penalty perhaps for man's erect posture. But focal necrosis and plates of calcification were local and limited in their occurrence and might be met with in any, often in the most unexpected, parts of the arterial system. They resembled the results of injury (as in the popliteal where they are so common) or the blocking of the capillary area of the vasa vasorum. The effects of these two sets of changes are also somewhat different. The consequences of arterial hypermyotrophy, cloudy and granular degeneration, the generalised changes, were primarily to disturb the dynamics of the circulation and the nutrition (e.g., the elasticity and contractility of the vessels and the cardio-vascular balance). The effects of the necrosis, on the other hand, were local and led to rupture and hæmorrhage. Necrosis of the media, which was not infrequently associated with arterial hypermyotrophy, if unaccompanied by compensatory adventitial or intimal thickening, appeared to be one of the most insidious and lethal of medial degenerations (Fig. 6). It might be present in one or two spots in an arterial system which, excepting for hypertrophy, might be otherwise absolutely normal. Consequently these spots are very difficult to find, but my belief is that they exist (in association with arterial hypermyotrophy) in a large proportion of cases of cerebral hæmorrhage. Such an association was found in at least four of the six cases of cerebral hæmorrhage among the 30 cases submitted. It may have been overlooked in the other two in spite of the most careful search.

ARTERIAL HYPERMYOTROPHY.

Arterial hypermyotrophy was a term I first used in 1891[9] and again in 1897[10] to describe an increased thickness of the muscular tunic of the arteries due to an increase in volume or number, or both, of the individual muscular fibres. A numerical increase is very difficult to determine. The question whether an increased volume or swelling of the individual muscular fibres is to be called a hypertroph is an important one. I still regard the condition as primarily a genuine muscular hypertrophy, just as an increased thickness of the cardiac wall in which some or all of the muscular fibres are swollen is also so regarded. My subsequent researches with acid and neutral orcein have, however, revealed a certain cloudiness of the protoplasm of the muscle in some cases in which other stains did not reveal it. This nebular condition, as I have just mentioned, is probably the earliest stage of degeneration. But the fact of degeneration having commenced by the time a case reaches the post-mortem room does not negative the existence of hypertrophy. In point of fact, arterial hypermyotrophy must be regarded—an opinion shared by Dr. William Russell[11]—as being the first step to most medial degenerations, the earliest phase of medial sclerosis, the first change when a strain is thrown on the arteries; hence the importance of its recognition.

Arterial hypermyotrophy, as thus histologically defined, constitutes, in my experience, a distinct clinical and pathological condition of prolonged course, capable of recognition during life by careful investigation,[12] characterised in the first stage mainly by "postural" vertigo and other symptoms of high and unregulated blood pressure; in the second stage mainly by the evident thickness of the arteries, cardiac hypertrophy, and sometimes by cerebral or other hæmorrhage; and in the final stages by the various circulatory and nutritional disturbances which may ensue. Sometimes, but not necessarily, it is associated with chronic renal disease, which is only one amongst many of its causes and it constitutes in itself one of the main pathological conditions on which cerebral and other hæmorrhages depend and on which the incipient phenomena of "senile decay" also depend. During the 19 months June 1st, 1890, to Dec. 31st, 1891, there were 257 necropsies made at the Paddington Infirmary. 28 of these 257 cases were patients who had presented circulatory symptoms or accidents during life but who had no cardiac valvular disease. It was the combination of these two circumstances which induced me specially to investigate the arterial system. The muscular tunic of every one of these cases was increased in thickness, in many it was associated with other morbid changes in the media, and in some cases with abnormalities in the other arterial tunics. Two similar cases (No. 41, a case of accidental death, and No. 42, an interesting case of arterial hypermyotrophy in which the patient died in the Paddington Infirmary in the spring of 1892) are added to this list, making 30 in all. Clinical and pathological details of these cases and the methods adopted in the examination are given in the appendix.[13] Measurements were made of the muscular and other arterial coats by means of an eye-piece micrometer; the lumen was also measured and allowed for. Upwards of 1500 microscopic specimens of arteries were examined, measured, and compared with normal specimens, an average of 50 sections to each case, taken from arteries of various sizes of the limbs, abdomen, thorax, and head, as well as the arterioles of the viscera. These 30 cases have been arranged in two groups. Group A comprises 17 cases in which the arterial hypertrophy was *relatively* uncomplicated by other arterial disease and by less advanced degeneration of the tunica media. Group B comprises 13 cases in which the arterial hypermyotrophy was complicated more or less with advanced degeneration, dilatation, or other arterial disease—viz., intimal or adventitial sclerosis or atheroma. These cases represented the later stages.

The difficulties of an inquiry such as this were considerable. 1. The universal distribution of the arterial system makes these examinations most tedious and prolonged and the extensive dissections required often prevent one getting permission from friends. 2. Two or three sections of an organ will give you a good general idea of its morbid changes, but this is not so in the arterial system when 50 sections sometimes seem inadequate. 3. The minuteness of the measurements render the greatest care and precision necessary. 4. The state of contraction or dilatation of an artery is only one of the many conditions for which allowance has to be made in measuring the muscular tunic. If an artery is in a state of contraction the media is, of course, thickened, whether there be hypermyotrophy or not, and the intima is thrown into folds; if it is dilated the media is, of course, thinned and the intima stretched. No medial measurements therefore are of much value unless the calibre of an artery as compared with a normal specimen is measured and recorded. 5. Considerable difficulty is very often experienced, especially in degenerate arteries, in distinguishing the boundaries of the middle coat, and after trying auric chloride, nitrate of silver, and many other stains I found in acid orcein an ideal stain which brought out into marked prominence the elastic layer of Henle and the increased quantity of elastic tissue which is found in the inner layers of the adventitia. 6. But perhaps the greatest difficulty of all consisted in securing a normal standard from which measurements and comparisons could be made. In my search for a normal standard I found, as already mentioned, that there was certainly a minute variation in the thickness of the tunica media in various conditions, both in health and disease. After examining several bodies in which death occurred from acute or chronic disease, at last I procured some specimens from persons who had died from accident in the midst of apparent health.

As examples of arterial hypermyotrophy I will refer to three cases which represent the three stages of the disorder: (1) simple hypermyotrophy; (2) hypermyotrophy with incipient degeneration; and (3) hypermyotrophy with degeneration, dilatation, and compensatory intimal and adventitial sclerosis.

1. In the course of my search for a normal standard I had, by the courtesy of Dr. Danford Thomas, the opportunity of examining the body of a man, aged 30 years, who was riding his bicycle across Oxford-circus when he came into violent collision with the shaft of a four-wheeled cab, which smashed his ribs into his liver, and he died in 12 hours. The case may be regarded as being one of arterial hypermyotrophy in its earliest phase when the *media is free* from degeneration of any kind. The average of 40 specimens of arteries and organs examined in this case showed an increased thickness in the muscular tunic of the arteries of $\frac{3 \cdot 3}{2 \cdot 5}$. The heart was slightly hypertrophied and weighed 11½ ounces and the muscular tissue was quite healthy. All the other organs were normal. After some difficulty I traced his wife who informed me that he had always seemed quite healthy but complained a good deal of headaches. I am glad to have been able to exhibit this case because arterial hypermyotrophy is not very often met with in the post-mortem room in such an early and unmixed condition. There was, as far as I could tell with the means

at my disposal, a numerical increase in the muscular fibres but this young man's arteries (e.g., the radial and anterior tibial) also revealed an increased thickness of the individual fibres. I have sometimes been asked if such thickening does not indicate degeneration rather than hypertrophy. Now, the individual fibres of all contracted arteries are thickened and I have repeatedly seen the same thickening with or without contraction in normal arteries taken from young and perfectly healthy subjects; there is a remarkable variation in this respect within the range of health. True degeneration is revealed by granular (and perhaps cloudy change) or other definite changes in texture.

2. The following case (Case 42) may be regarded as a fair example of arterial hypermyotrophy terminating at a relatively early phase of the disorder in cerebral apoplexy. A man, aged 56 years, was admitted into the Paddington Infirmary on April 14th, 1892, for left hemiplegia, which had come on suddenly while he was at work the day before without loss of consciousness. The præcordial dulness was extended and the apex beat was forcible. The pulse was full, *the arterial tension was high, and it was noted by one of* my colleagues that "the artery feels like whipcord." The abdominal organs were natural. There was incontinence of urine but some was collected and it was noted as being copious, clear, pale, acid, specific gravity 1020, with no albumin or sugar. We were informed that his mother had incurred a stroke of paralysis down one side, followed by death two years later, and that one sister was in an asylum. His brother, aged 58 years, had previously been in the infirmary for "bronchitis" and there was a note in our records that he also had "whipcord-like arteries" and complained of "giddiness when he stooped." The patient's previous history revealed that he had taken both beer and spirits in fairly liberal quantities but not to what was regarded as excess. He had suffered from "bronchitis" from time to time. For the past two years he had been troubled with swimmings and giddiness in the head, especially after stooping, had complained of a good deal of headache, occasional breathlessness, and depression of spirits.

comatose and died

out fresh symptoms.

was found excepting in the vascular system. The right kidney weighed four ounces and the left four and a half ounces; microscopically they were quite normal, excepting that the arterioles stood out and remained patent. Microscopically the media of the arterioles was thickened but the parenchyma was perfectly normal. The heart weighed 13 ounces and its walls were notably hypertrophied and slightly dilated. The muscular tissue appeared normal to the naked eye and under the microscope. The valves were perfectly healthy. A naked-eye examination of the arteries showed that the radials and all the other arteries of similar and smaller size were slightly contracted, with the single exception of the dorsalis pedis on both sides, which was dilated, and that the muscular coat of *all the arteries* was notably thickened even after allowing for the slight diminution of calibre. The brachials, radials, and femorals were tortuous, showing an increase of the media in length as well as in thickness. Microscopically, sections of over 50 different arteries were examined and measured, the average measurements being, calibre $\frac{18}{20}$, media $\frac{4\cdot5}{2\cdot5}$, adventitia $\frac{2}{2}$, and intima $\frac{1}{1}$.[14] The increase in the muscular tissue was most marked in the lower extremities; the average was $\frac{5\cdot7}{2\cdot5}$, that of the upper

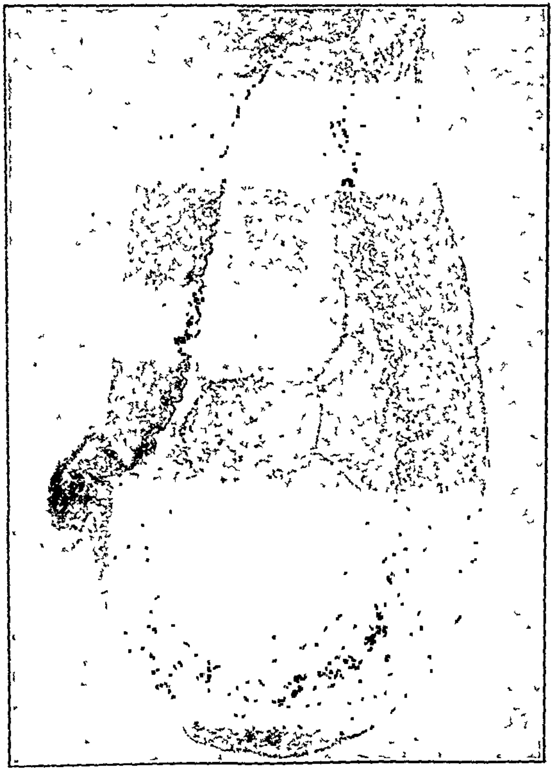
[14] These figures represent divisions of the eye-piece micrometer. The upper measurement is the actual measurement of the artery under examination; the lower represents the measurement of a normal

labour, for the fraction already expresses a ratio of abnormal to normal.

extremities and abdomen being $\frac{4\cdot1}{2\cdot5}$ and the splenic artery $\frac{4\cdot0}{3\cdot0}$. In the radial (Fig. 4) the thickening of the media was very marked, the measurements being $\frac{20}{20}$, $\frac{5\cdot5}{2\cdot5}$, $\frac{2}{2}$, and $\frac{1}{1}$. The muscular tissue of the arteries appeared to be normal and free from degeneration excepting a moderate degree of cloudy swelling in the inner layers of the media in the arteries of the lower extremities. In the arterioles of the viscera the muscular tissue was increased, but less than in the arteries of the limbs and abdomen. A slight amount of intimal thickening could also be observed in the arteries of the lower extremities. Elsewhere the tunica intima was normal. The adventitia was not notably increased or condensed anywhere (excepting perhaps in the radial and dorsalis pedis arteries). The cerebral vessels appeared to be remarkably healthy both to the naked eye and microscopically and I was at a loss to know why this patient should get hæmorrhage in this situation. There were no atheroma and no thickening in any of the coats to be detected. The media was perhaps slightly increased but the increase was hardly measurable. Nevertheless, in the centre of the brain, which was otherwise quite healthy, there was a recent blood clot of about the size of a hen's egg, occupying the right internal capsule. These were the results of going twice over the specimens of more than 50 arteries. When all the arteries are simply too thick why should they rupture? The most obvious explanation was that the marked hypermyotrophy of the systemic arteries and the heart threw an extra strain on the relatively unhypertrophied arteries of the brain, and I think this explanation is sufficient, or partly sufficient, to account for many cases of apoplexy. But on further search of additional sections I came across a minute (microscopic) necrotic focus in the tunica media, surrounded on all sides by healthy muscular tissue, in four situations, one in a section of the radial, one in an arteriole in the kidney, one in the basilar artery, and one in a section of the middle cerebral artery (Fig. 6) which was bulging. I think it is safe to infer that this man's cerebral hæmorrhage came through such a bulging. But one meets with other cases of medial necrosis without cerebral hæmorrhage, therefore the cardio-arterial hypermyotrophy and its consequent high tension must, I think, still be regarded as the main cause of the cerebral hæmorrhage in this case. It is in many ways a most instructive one, uncomplicated as it was with any renal disease and unmixed to any extent with intimal or adventitial sclerosis or with those extensive degenerative changes in the media which so often supervene (e.g., Cases 58 to 70[15]) before the patient reaches the post-mortem room.

FIG. 6.



Middle cerebral artery (logwood stained, × 40) of a man, aged 56 years, the case is described in the text. There was, *as usual in the cerebral arteries in cases of arterial* hypermyotrophy, only very slight hypertrophy of the media. But a minute focus of necrosis has resulted in bulging, such as would give rise, when combined with high tension, to the hæmorrhage from which he died.

3. The third case, taken from among many similar ones, illustrates the final stage of arterial hypermyotrophy when degeneration, dilatation, and intimal and adventitial sclerosis had supervened (Fig. 3). A man, aged 73 years, had been many years in the workhouse and was for four and a half years under observation in the Paddington Infirmary. Since the age of 59 years he had been subject to vertigo, especially on any change of posture, *which was at first relieved by nitroglycerine.* At the age of 71 years the vertiginous attacks were replaced by attacks of syncope, sometimes even while he lay in bed. He died suddenly in one of these syncopal attacks at the age of 73 years. The kidneys (the total weight of which was nine and a half ounces) and other organs were healthy and the urine was always normal. The heart was hypertrophied, the weight being 19 ounces. The brachial artery compared with that of the patient aged 100 years, whom I have already alluded to, depicts the muscular increase (Figs. 2 and 3). The calibre of these two arteries was the same and therefore their tunics are strictly comparable. The patient's hypermyotrophy was widespread, more marked in the lower and less marked in the upper half of the body, and least marked in the brain. Some degree of degeneration of the media existed in the lower parts of the body; there was cloudiness in the upper. Dilatation (average $\frac{27}{20}$) and tortuosity with some degree of intimal and adventitial sclerosis existed, most marked in the larger arteries and those of the lower limbs. Some atheroma existed in the largest vessels only. In all the other cases submitted with this paper the leading symptoms during life were circulatory, and the leading change after death was cardio-arterial hypertrophy, many of them, as already explained, being mixed when they reached the deadhouse with degeneration or other conditions. For instance, in Case 48 (Group A), a man, aged 65 years, a case of senile vertigo, who died from cardiac failure, the tunica hypermyotrophy, which amounted in some places to $\frac{6\cdot1}{2\cdot5}$, was associated with marked dilatation (amounting sometimes to $\frac{47}{20}$) and some generalised intimal sclerosis. In Case 60 (Group B), a woman, aged 76 years, a case of chronic interstitial nephritis, who died from uræmia, the hypermyotrophy averaged $\frac{4}{2\cdot5}$ and was associated with some degeneration and dilatation in the larger arteries and contraction in the smaller arteries. In Case 70 (Group B), a man, aged 75 years, a case of giddy, fainting, and cyanotic attacks, who died from "senile decay," the hypermyotrophy was associated with degeneration, dilatation, and slight generalised intimal sclerosis.

In all the 30 cases which are submitted the muscular coat of the arteries was increased in thickness, even after making allowance for any dilatation or contraction of the vessel. Microscopic measurements showed that the average increase in the muscular tissue of the arteries of the 17 cases in Group A was nearly 50 per cent.—i.e., one and a half times the normal. The greatest average increase was $\frac{12}{5}$ and the smallest $\frac{7}{6}$ of normal. In Group B the average was about 31 per cent. The increase in the muscular coat had in most instances taken place in length as well as in thickness, so that the artery had become tortuous. A thickened tunica media when fairly marked can after a little practice be detected by the naked eye or with the aid of a one inch Codrington lens. The vessel loses some of its pliability, remains unduly patent, and does not collapse as a normal artery does. The media may even project beyond the intima and adventitia as though their connexions were loosened. Histologically the change I am referring to is not a fibrosis even in the arteries and arterioles, for the rod-*shaped nuclei could always be revealed* when the section was efficiently and thoroughly prepared (see schedule of cases[16]) As regards *distribution*, I found that the radial artery might be regarded in most cases as a tolerably fair sample of the thickness of the muscular tunic throughout the arterial system, though by no means of its condition as regards degeneration The media of the arteries of the lower extremity was nearly always more hypertrophied (and presented a more advanced stage of degeneration) than those of the upper extremities and these latter were more affected than those of the brain The different arteries of a limb might vary considerably among themselves both as regards thickness and degeneration The middle coat of the cerebral arteries was often quite normal in thickness The major distribution in the lower extremities suggests the explanation that gravity throws more strain upon these latter and that the relative exemption of the cerebral arteries was due to the same cause Dr Oliver s and Dr Hill s observations[17] support this view This relative exemption of the cerebral vessels from the thickening of the media probably helps, as previously mentioned, to explain the frequent occurrence of cerebral hæmorrhage in cases of arterial hypermyotrophy

---

[15] See Appendix in the Transactions of the Pathological Society of London, 1904.

1 Among the *causes of arterial hypermyotrophy* the first question which claims our attention is its relation to chronic renal disease The late Sir George Johnson[18] first demonstrated muscular hypertrophy in the systemic arteries and arterioles of the kidney in association with chronic renal disease and this has been confirmed by others[19] Undoubtedly chronic renal disease is very constantly accompanied and followe[illegible] d is what one w[illegible] hich is so usual [illegible] cannot be regard[illegible] rophy, for out of [illegible] could be classed as suffering from chronic renal disease—four out of 17 in *Group A (Cases 43, 46, 51* and *Case 44* who presented alcoholic fatty degeneration of all organs[20]) and five out of 13 in Group B In the remaining two thirds (21 cases) there were no urinary changes during life and no evidence of renal disease after death It is now universally admitted that a slight degree of fibrosis in all organs is normal and usual in the aged, but this is not likely to be mistaken for incipient interstitial nephritis especially when the urine has been normal during life and the weight and macro and microscopic characters of the kidneys are natural Since the days of Mahomed Ewald and others (1881) the meaning of the term "chronic Bright s disease' has by some been extended so as to connote [illegible] sease followed by arterial [illegible] generalised morbid condition [illegible] gh arterial tension various circulatory and nutritional defects associated or followed with more or less indefinite evidences of renal disease I wish in the first place to protest against the name of Bright being applied to any but cases exhibiting definite evidences of renal disease during life and after death Such a confusion is undesirable and unnecessary Secondly, I would submit that the *generalised* clinical condition to which I have just referred as being called by some chronic Bright s disease corresponds anatomically with cardio arterial hypermyotrophy and its consequences, and clinically with the senile hyperpiesis described by Professor Clifford Allbutt[21] or some other form of high tension with its concomitant circulatory and nutritional defects Thirdly, my investigations prove that although chronic renal disease is a potent agent it is not by any means the only cause of arterial hypermyotrophy

2 Hypertrophy of the heart may well be regarded as in some way *causally related to arterial hypermyotrophy* either may be the cause of the other or both may be the product of a common cause It existed in all of the 17 cases of Group A the average weight being 13 9 ounces two being as high as 19 ounces In none of these did any valvular disease exist six cases of arterial hypermyotrophy with cardiac valvular disease having been excluded from the list on this account In Group B the average weight of the heart in the 13 cases was 12 5 ounces, one being as high as 17 5 ounces In persons whose ages were mostly over 60 years it is not to be expected that the heart though hypertrophied will always be free from degenerative changes Nevertheless, in 13 the microscopic structure was healthy or exhibited only the 'brown atrophy of the aged Fatty degeneration existed in three cases fibroid degeneration in six cases and some granular degeneration in ten cases the pericardium was adherent in three case[illegible] from these data is that the [illegible] trophied in cases of arteri[illegible] my belief is that if the arterial system were oftener investigated in cases of *cardiac* hypertrophy some *arterial* hypermyotrophy also would be found and much light thus be thrown upon the subject It is only natural that the opposing forces of the heart and arteries should act and react on each other But which of these first hypertrophies or whether, as seems possible, they both start at the same time and, finally, which first begins to give way and to degenerate and to dilate must, generally speaking, be matters of conjecture

3 High arterial tension, sometimes intermittent but usually persistent, has existed in all the cases of arterial hypermyotrophy which I have observed before arterial dilatation or degeneration has occurred and in many cases after this has taken place This was estimated by the finger and [illegible] seen after [illegible] or clinical [illegible] gh tension having existed antecedently to the occurrence of any arterial hypermyotrophy, but in view of the well known fact that excessive functioning, in health at any rate, produces over growth and the frequency with which the known causes of high tension could be revealed in the history of the cases submitted it seems extremely probable that high arterial *tension is the main cause of arterial hypermyotrophy* For instance, in the 17 cases in Group A there was a history of alcoholic excess in seven of gout in two, of passing gravel or lithates in six, chronic renal disease existed in three, and in the remaining case there was no information of value on the point My belief is that these figures represent approximately the truth about the matter and that alcohol in anything more than medicinal doses plays the leading rôle in this and other medial changes, sugar in excess perhaps coming next

4 Heredity and age no doubt play their part in causation But the information before us is not sufficient to draw any very definite conclusions The average age at death of 16 out of the 17 cases in Group A (excluding Case 41 who died from accident) when they reached the post mortem room was 66 5 years but this is no guide as to when the condition supervened It may have existed 10 or 20 years in some two or three in others, many had had symptoms for years Three died at 38 42, and 56 years of age from cardiac failure uræmia and cerebral hæmorrhage respectively, the remainder were over 60 years of age when they died In Group B the average age at death was 74 5 years These were cases in which the media presented marked degeneration and which were complicated by other arterial disease

The *consequences* of arterial hypermyotrophy seem to be mainly the same as those of high arterial tension—namely hypertrophy of the heart and subsequent degeneration of the cardio arterial system with disturbance of the functions of all organs Cardiac hypertrophy has already been alluded to 1 Undoubtedly one of the most serious consequences is cerebral hæmorrhage It occurred in four cases in Group A and two in Group B This seemed to be due not so much to the hypermyotrophy in the media of the cerebral arteries *themselves as to the relative immunity of these vessels* Arterial hypermyotrophy being most marked in the systemic arteries the rigidity of these vessels throws a strain on the least protected part and any excessive cardiac hypertrophy undoubtedly contributes to this end Further, when describing Case 42 I alluded to the possibility of minute foci of necrosis which might easily be overlooked, also forming an important factor in cerebral and other hæmorrhages It will be noticed that hæmorrhages in other situations than the brain, epistaxis dermal hæmorrhage frequently arose in several of the cases more particularly in Group B cases in which degenerative changes in the arteries were most marked Cerebral accidents other than cerebral hæmorrhage occurred in only one case in Group A and in four cases in Group B 2 Reference has already been made to various degenerative changes in was very ill. The next morning his temperature was 100° and at midday 99°.

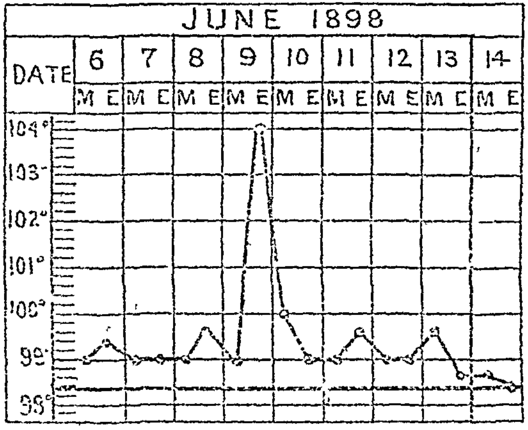
[21] THE LANCET Jan 17th 1903 p 170

The question now was could anything more be done for him. All his future prospects were being ruined by his continued absence from school and although he had now been running wild for some months his "heat centre" was apparently as "imbecile" as it had ever been. In the course of the previous year I had discussed the condition with quite a number of medical men whom I had met in consultations and no two of them had ever agreed as to the diagnosis. The most thought that there was some obscure tuberculous condition which we could not find, some thought it was worms, while one very eminent throat specialist kindly offered to operate on him for adenoids, as he had known several cases in which similar attacks of fever had disappeared after this operation. I determined that I would take the boy quite independently to two eminent medical men and if they differed in opinion to ask a third to review their decision. He first saw Dr. Eustace Smith, who entered fully into his case, examined him thoroughly, and said that he considered it all a question of "acute gastric catarrh" due to diet, and he gave the following dietary. The following were to be avoided: starchy puddings, jam, honey, marmalade, &c., fruit, raw and cooked, potatoes, turnips, carrots, sweet cakes, and oatmeal porridge. The following were allowed: beef, mutton, birds, fish, bacon, ham, tongue, eggs in any shape, green vegetables, bread and butter; puddings: custard, batter, bread and butter, light suet pudding, pancakes, rusk pudding, blancmange made with gelatin, stewed figs and prunes, and bananas. Dr. Smith also recommended a particular kind of bath. The boy was to sit in water of a temperature of from 100° to 105° and was to be sponged with this. Finally he was to have a douche down his back of water of a temperature of 75° poured out of a jug. He was then to be well rubbed with a towel. Dr. Smith considered that this bath hardened the system and prevented the tendency to catarrh. I next took the boy to Dr. (now Sir Thomas) Barlow, who also fully entered into the case and expressed in almost identical terms the same opinion as Dr. Smith. So much was this the case that both Dr. Smith and Sir Thomas Barlow stated that they did not often see a case in which the fever rose so high as 104° from this cause and both expressed the opinion that the whooping-cough had left the boy's nervous system especially susceptible and that the height of the fever was due to this condition left by the whooping-cough. Sir Thomas Barlow recommended precisely the same diet with one important addition—that we might sometimes give potatoes fried quite dry as chips. He did not mention the bath. I had not expected that the opinions of these two eminent physicians would have so entirely coincided and having an *appointment* with Sir William Broadbent I took the boy to him. I told him exactly what had taken place and said I thought that I need not trouble him in the matter. He, however, examined the boy carefully, came to the conclusion that there was no evidence of any disease, and agreed with Dr. Smith and Sir Thomas Barlow as to the cause of the attacks.

CHART D.



I returned to Exeter very much gratified by the result of my visit to London. We had at last found out a cause which might account for the "imbecile condition" of the boy's "heat centre." But I confess that I was not yet convinced that we had found the final cause of the fever. In former years I had passed some 18 months as resident medical officer of the Evelina Hospital for Sick Children and I had never recognised such a cause of fever. Amongst others I had discussed the condition with a friend who very recently had been resident at the Hospital for Sick Children, Great Ormond-street, and he was as ignorant on the subject as I was myself. Still we determined to give the treatment a thorough trial; we adopted the diet and the bath and watched the temperature. Within ten days the temperature became normal and there it remained more or less entirely ever since. We sent the boy back to school; at first for half the day, then for the whole day, and he never had another attack. He then went to a boarding school where his dietary could be kept up and he did well. After two years gradually he went back to a fuller diet: to potatoes carefully cooked, to a certain amount of milk pudding, and as he grew older he began to take a certain amount of jam. Then he passed into the Navy and on the *Britannia* he fed exactly like the other boys and he is now a midshipman leading just the ordinary life of the Navy and he is as strong, as well developed, and as good at athletics as any other boy of his age. I said that he never had another attack after his taking this diet. This is not quite accurate, for he had one attack about a year after he commenced it. He then had a good helping of black currant tart with sugar and cream and that evening he had a temperature of 102° which went down the next day. After this his diet was more strictly kept until he went to the *Britannia* (aged 14 years and three months) and he never had another of the attacks. I venture to think that this solitary attack within a few hours of eating the black currant tart, sugar, and cream is of more significance as indicating the dependence of these attacks on certain articles of diet than any other fact which could be put forward.

Now since I have known this cause of fever in 1898 I have met with some eight or nine similar cases of which I have more or less accurate records. In all these cases the children have been much under their proper average weight for their height and age. In every case the stomach has been very much distended. Sometimes there have been definite histories of more or less frequent feverish attacks, whilst in some cases the children have been observed to be flagging and below weight and then the temperature has been observed to be always above normal. In those cases in which attacks of fever have occurred the cause had never previously been recognised. In some cases the attacks were termed influenza, in some febricula, while in one case the child was said to have constantly recurring attacks of bronchitis in which, however, the ordinary symptoms of bronchitis were absent. In those cases in which the children were found to be flagging and under weight the temperature might be observed for some weeks ranging between 99·2° and 100° just as was noticed in my boy's case when at Budleigh Salterton. In every one of these cases the greatest improvement has followed the adoption of the diet recommended by Dr. Smith without the baths which I have rarely, if ever, ordered. As far as I know, a cure has resulted in all these cases, but I have not been able to follow them all sufficiently to state whether the cure has continued altogether.

Very little has been published on this subject; as far as I am aware the only reference to it is in Dr. Smith's large work on "Diseases of Children." I do not, however, quite agree with Dr. Smith's view as to how these various farinaceous foods act. When I saw him with my boy I understood him to hold the view that it was the "actual fermentation of these foods" which did the harm. But in a letter which he was good enough to write to me on Feb. 23rd, 1903, he corrected this view. In this letter he says:

"In these cases I do not attribute the fever to the irritation of fermenting food, although, of course, there is active fermentation going on in the alimentary canal, but to the catarrh, including the liver upset. The latter (the condition of the liver) has, I think, a *great* deal to do with the rise of temperature, for a dose of calomel or blue pill, which sets the liver working, generally puts a stop to the fever directly it has had time to act. I am constantly seeing cases like your boy and cure them always in the same way. One of the difficulties is to get mothers to realise how sensitive the children become to cold and one has to repeat this to them again and again; for as the child goes on catching cold upon cold—every time becoming more susceptible to chills—he becomes after a few months like a hot-house plant and the slightest exposure at once upsets his weakly digestive organs. To cure them you have to give them back their normal resisting power to chills and until you have done this they are never safe "

Now, Dr Smith has such an intimate knowledge of diseases of children in general and of this condition in particular that it is quite likely that the explanation of the fever is as he says But my experience of my own son's case and of all the other cases in which I have observed the condition leads me to a different conclusion I believe that the fever is due to an auto-intoxication from the products of fermentation of these particular mixtures of starchy foods The temperature shows, I think, that the attacks are much more like an auto sepsis than a catarrh Their more or less sudden onset and quick decline after a profuse perspiration appear to me very like what one would expect from absorption of a septic material from the alimentary canal The fact that in my experience these attacks cease when the particular foods which disagree are stopped, although all the other conditions of life remain the same, seems to show that these particular foods are the actual cause of the attacks We all know that *in very early life young children cannot digest starchy foods*, owing to the non-development of the pancreas at this time of life, and observations have been lately published in which at much later periods of life deficient pancreatic digestion has been observed I am inclined to think that in the cases in which I have observed the fever the pancreatic digestion is not proportionate to the age of the patient Starchy foods are not properly digested, especially certain starchy foods which by their structure (such as potatoes and carrots) or by their composition (such as combinations of sugar and starch in milk pudding and jams) are especially difficult of digestion As a result, undue fermentation of these foods takes place in the alimentary canal and causes the fever As the child grows older the power of his pancreatic digestion increases and so the cause of the fever gradually ceases The fact that a dose of mercury much assists these cases is, I think, in favour of this hypothesis, for calomel and blue pill are most powerful disinfectants of the bowel

I would notice one other point In my boy's case he always seemed worse when attending school I believe this is entirely to be explained by the fact that he hurried from breakfast to school and that his indigestion was increased by this proceeding But when his food was altered he still hurried from breakfast to school and *yet no attack of fever ever occurred* In cases of fever in children for which no obvious cause can be found it will therefore be advisable to try the effect of the dietary that Dr Smith and Sir Thomas Barlow recommended for my son

Exeter

AN ANALYSIS OF 150 CASES OF DEATH FROM BRONCHO-PNEUMONIA

BY PERCY HARDY, B A, M B, B C CANTAB,
M R C S ENG, L R C P LOND

THE cases under consideration are the total number which occurred, in children under 13 years of age, at the London Hospital from Feb 1st to Dec 31st, 1903, and of which post-mortem examinations were made Drawn, as they all were, from the East end of London, the children were among the poorest to be found anywhere in England and lived mainly under the most adverse circumstances The results of this analysis are no doubt very different from those which would be obtained from investigating cases of death from the same disease occurring in children of the middle and upper classes, and this applies especially to the effect of the manner of feeding I shall endeavour to show in this series that the feeding of the children by bottle instead of at the breast *increases the mortality enormously*, *but it must be* remembered that the former method of feeding means in the majority of these cases that the children get—not other milk so prepared that it resembles more or less completely human milk, as would often be the case in children of the middle and upper classes—but anything and everything which their parents eat and *which they can be made to swallow* *Thus* nothing is commoner in the East-end of London than for a mother to answer a question as to the feeding of her infant in arms by saying "It has just the same as what we have" No cases of acute miliary tuberculosis have been included, and indeed in only four out of the 150 were there any obvious signs of tuberculosis about them, and these were as follows, a caseating nodule at the apex of the left lung in one case, a healed calcareous nodule at the apex of the left lung in one case, and caseating mesenteric glands in two cases It perhaps is interesting to note in passing that there were no less than 23 of these children brought to the hospital in a moribund condition I have classified the results thus —

I —AGE AND SEX

1 *Age.*—All of the children were under 13 years of age

8 under 1 month *
3 between 1 and 2 months
9 " 2 " 3 "
20 under 3 months
17 between 3 and 6 months
18 " 6 " 9 "
18 " 9 " 12 "
73 under 1 year
27 between 12 and 18 months
19 18 24 "
119 under 2 years

119 (*carried forward*)
13 between 2 and 3 years
6 " 3 " 4 "
138 under 4 years
0 between 4 and 5 years
2 " 5 " 6 "
3 " 6 " 7 "
1 " " 8 "
1 " 8 " "
1 " 9 " 10 "
1 " 10 " 11 "
2 " 11 " 12 "
1 " 12 " 13 "
150

* *Of the eight children under the age of one month one was six days* old and seven were 14 days old

2 *Sex*—85 of the cases were those of males, while 65 were those of females

II —CAUSES

A —*Predisposing Causes*

1 *Feeding* —In counting up the number of breast-fed and bottle fed children respectively the following has been the principle adopted A child has been considered breast fed if he has been reared on the breast for a greater period than four and a half months or, if the child be less than nine months old, for a greater period than half his life, if fed on the breast for less than this he has been considered bottle-fed The instances in which this rule has had to be followed are —

Counted as Bottle fed

Age	Breast-fed for—
7 months	1 month
8 "	2 months
9 "	1 month
10 "	3 weeks
7 "	6 "
7 "	5 "
9 "	2 "
4 "	3 "
1¼ years	3 months
1½ "	2 "
1¾ "	4 "

Counted as Breast fed

Age	Breast fed for—
10 months	7 months
1¾ years	5 "
2½ "	8 "

On this plan it was found that out of the 64 cases of children under four years of age in which the method of feeding was known 32 were breast fed and 32 were bottle-*fed—that is, the deaths from broncho pneumonia were equal*

In order to determine the *average* proportion of breast fed to bottle fed children for that part of London 78 children who were brought to the hospital, either because of accidents, such as burns, scalds, and the like, or for other reasons than for advice or treatment and including no cases in which they were *brought for any medical* disease, were taken Of these it was found that nine were bottle fed—that is, 11 5 per cent —and 69 were breast-fed—that is, 88 5 per cent But it has just been shown that the number of deaths from [illegible] and breast fed childre [illegible] ality among bottle fed [illegible] it is, *the mortality from broncho pneumonia is 7 7 times as great in bottle fed as in breast fed children*

2 *Rickets* —There were well marked signs of rickets in 25 of the 150 cases, or 16 7 per cent Of the 95 cases between the ages of six months and three years there were 21, or 22 1 per cent while of the 59 cases between the ages of one and three years—the rickety period *par excellence*—there were no less than 15, or 25 4 per cent, showing well marked signs of this disease

B —*Exciting Causes*

1 *Acute specific fevers* —(*a*) Measles —In 15 cases the disease occurred during, or followed immediately on, an attack of measles Of these, four patients were under the age of one year, five were between one year and two years,

three between two and three years, two between three and four years, and one was between six and seven years. (*b*) Diphtheria.—12 cases occurred during an attack of diphtheria. Of these, one patient was under the age of one year, six were between one and two years, two between two and three years, and three between three and four years. (*c*) Whooping-cough.—Of the seven cases in which the child was suffering from whooping-cough two patients were under the age of one year, three were between one and two years, and two were between three and four years.

2. *Meningitis.*—Eight cases occurred during an attack of meningitis. Of these five were of the epidemic cerebro-spinal type while two were those of suppurative meningitis secondary to suppurative otitis media. In one case the skull was not allowed to be opened but the child presented the symptoms and signs of meningitis.

3. *Suppurative otitis media.*—There were five cases of suppurative otitis media, three affecting the right ear alone, not any affecting the left ear alone, and two affecting both ears.

4. *Pyæmia.*—In three cases the broncho-pneumonia was part of a general pyæmia.

5. *Anæsthetics.*—In three of the cases the broncho-pneumonia was thought to be probably due to the administration of an anæsthetic which preceded the attack.

6. *Typhoid fever.*—Two of the children were suffering from typhoid fever.

7. *Scalds and burns.*—There were severe scalds preceding the illness in two instances. In one case, brought in dead, the skin showed signs of a superficial burn which had probably occurred several days previously.

In one case the broncho-pneumonia followed the impaction of a coin in the œsophagus and in another it was secondary to erysipelas. The onset of the illness was marked by an attack of diarrhœa and vomiting in 21 of the cases.

III.—MORBID ANATOMY.

1. *Distribution.*—The right lung was alone affected in nine cases, the left being alone affected in nine cases also. Both lungs were affected in 132 cases.

2. *Variety.*—(*a*) Confluent or massive broncho pneumonia (in which one or more lobes were completely solid and resembled to a greater or less extent lobar pneumonia).—Of this condition there were six instances, one being of the right lower lobe, two of the left lower lobe, and one of both lower lobes. In two cases nearly the whole of both lungs was solidified. (*b*) Suppurative broncho-pneumonia.—Of the 15 examples of suppurative broncho-pneumonia four were associated with suppurative otitis media, four with empyema (of these two with purulent pericarditis also), two with peritonitis, and three were part of a general pyæmia, while one occurred with acute suppurative periostitis.

3. *Coexisting pleurisy.*—(*a*) Acute fibrinous pleurisy.—Of the 15 cases in which this condition was present, in four it affected the right pleura only, in five the left pleura only, and in six it affected both pleuræ. (*b*) Pleurisy with effusion.—i. Serous: This was only present in one instance. ii. Purulent (i.e., empyema): there were 16 cases in which this condition was present, six affecting the right pleura, eight the left pleura, and two both pleuræ.

My sincerest thanks are due to Dr. R. N. Salaman for his kindness in placing all the post-mortem records, which he had so ably classified, at my disposal, and to the members of the staff and registrars of the London Hospital for their permission to use the clinical notes of the cases under consideration.

Nottingham.

A PLEA FOR THE MORE EXTENSIVE USE OF TUBERCULIN AS A CURATIVE AND PROPHYLACTIC MEASURE.

BY ALBERT S. F. GRÜNBAUM, M.A., M.D. CANTAB., F.R.C.P. LOND.,
FORMERLY ASSISTANT PHYSICIAN, LIVERPOOL HOSPITAL FOR CONSUMPTION, ETC.

IN a recent article Dr. C. Spengler of Davos reports two cases, verified by necropsy, of miliary tuberculosis cured with tuberculin. In the German literature it is easy to find records of many cases illustrating the utility of tuberculin as a therapeutic agent. In this country its use for curative purposes is almost in abeyance. I believe this to be a concession to popular prejudice rather than the result of unfavourable experience; indeed, I find that superintendents of sanatoriums have often no experience in the matter. Yet the clinical results more than justify the use, even if it were impossible to give any rational explanation of the action of tuberculin. But there is every reason for believing that it does stimulate the production of protective bodies against the tubercle bacillus. Although it looks like increasing the dose of poison, the injection of tuberculin is not really contra-indicated by the pre-existence of infection. For at the site occupied by the tubercle bacilli, in a progressing case, the cells are obviously too weak to resist the invader. But the other cells of the body have no opportunity of producing protective substances in the absence of a suitable stimulus, and the tubercle bacillus with its products does not come to them. It is the tuberculin which supplies this stimulus and it has been definitely shown by A. E. Wright that the injection of tuberculin leads to the increase of at any rate one class of protective bodies.

Since its introduction I myself use only the Neu-Tuberkulin (Bacilli Emulsion) of Koch and I proceed according to the instructions supplied with it, avoiding violent reactions. For the first part of the time the patient is kept in hospital; later, when the dose has reached 0·75 cubic centimetre, above which I do not usually go, one injection is given every week in the out-patient room, the patient remaining at home on the following day. But I never repeat an injection until the patient has clinically recovered from the one before. The total period of injections extends over three to six months.

In my own experience I have not seen any other of what may be termed the non-specific forms of treatment produce results approaching those of tuberculin in cases in the same stage of the disease. Many patients, of course, improve or recover under ordinary treatment or in sanatoriums. But such cases lack the specific resistance induced by the tuberculin treatment and easily relapse. The tuberculin treatment, like every other, has also its failures to record, but not, I think, so many, all things being equal, as the sanatorium treatment.

The best method is the combination of tuberculin and sanatorium treatment, first insisted on by Petruschky. But the latter portion is not always available and is expensive; the former can more often be carried out.

Now that the effects of tuberculin can be gauged it would seem rational to use it also prophylactically, especially in cases of obvious tuberculous diathesis, the predisposition of which it may be possible to gauge by Wright's methods. It seems to me from an examination of the evidence that in refusing to make therapeutic use of tuberculin (in suitable cases) the physician assumes the grave responsibility of rejecting one of the very small number of *specific* remedies for disease.

Leeds.

A CASE OF PERFORATED DUODENAL ULCER; OPERATION; RECURRENT HÆMORRHAGE; GASTRO-ENTEROSTOMY; RECOVERY.

BY HERBERT W. ALLINGHAM, F.R.C.S. ENG.,
ASSISTANT SURGEON TO, AND LECTURER ON OPERATIVE SURGERY AT, ST. GEORGE'S HOSPITAL;
AND
REGINALD THORPE, M.R.C.S. ENG., L.R.C.P. LOND.

AS the number of cases of perforated duodenal ulcer with operation and recovery is at present very limited we have thought that it is desirable to publish notes on the following case. The clinical history commenced some three years ago.

The patient, a man, aged 42 years, had an attack of hæmatemesis in June, 1901. This was treated on ordinary lines and quickly ceased. The stomach was found on examination to be somewhat dilated. After the attack he was apparently restored to his usual health, but in August of the same year a second hæmorrhage occurred which again quickly subsided with the same treatment as before. These attacks recurred at the following dates: March, 1902; October, 1903; and January, 1904; in the interval the patient was apparently well. Nausea and the vomiting of brown fermented fluid usually preceded the attacks of hæmorrhage Pain was never a prominent symptom although at the time of the hæmatemesis there was much abdominal discomfort and perhaps some pain of a "colicky" description The physical signs of dilatation became more and more pronounced There was no tenderness but always much "splashing" This could be heard *occasionally even at a distance from the patient on sudden* movement—i e, turning in bed or on a couch The contents of the stomach could be felt to strike against the thumbs when the hands were placed on each side of the abdomen over the epigastric region General nutrition was well maintained, the patient never becoming emaciated As " [illegible] ceased and hæmorrhage recu [illegible] thought desirable to put him [illegible] a milk diet and to keep him at rest in bed *He* was seen in consultation *with Dr* J F Goodhart in February, who advised further rest and a continuance of the milk diet The consultation was held with the object, if possible, of determining the exact cause of the hæmorrhage and of locating it It was thought possible that the bleeding was associated with hepatic trouble, and the exhibition of small doses of magnesium sulphate was decided on with the object of lessening any congestion of the liver that might be present and of aiding the portal *circulation Under this treatment* the patient appeared to improve and after several weeks' rest was allowed to get up and by April 3rd was apparently quite himself and was taking ordinary food On the night, however, of that day he had a great deal of abdominal pain and during the night was repeatedly sick vomiting brown fermented and very offensive fluid in much larger quantity than had been ingested within the previous 24 hours On seeing him all food was stopped by the mouth and he was treated as before, it being *hoped that the attack would subside as hitherto* On the 4th hæmorrhage recurred and he was in a good deal of pain As his condition was obviously serious, the hæmorrhage being more severe than in previous attacks, Mr Allingham was asked to see him, which he did on the afternoon of the 5th By that time as the bleeding had ceased and the patient's condition had improved, there being no pain and but little discomfort, it was thought best to continue the treatment hitherto adopted and not to operate for the dilated *stomach for ten days or so in order* to give the patient time to rally from the effects of the bleeding During all these attacks of hæmorrhage there was never any bright-coloured blood vomited, it was of the "coffee ground" character, and the stools for some days afterwards were quite black The character of the blood vomited doubtless was a sign that either it was due to repeated small hæmorrhages in the stomach or hæmorrhage beyond the pylorus with regurgitation At 10 P M on April 5th, whilst *the patient* was *absolutely at rest in bed, he* was *seized* with sudden intense pain in the abdomen which radiated upwards over the hepatic region and downwards to the right inguinal region with much pain in the right testicle He was intensely collapsed and had raised himself into a sitting posture with the object of relieving his agonising pain From the history of the case in conjunction with the onset of these symptoms

dulness was present or absent It was then decided to ask Mr Allingham to operate and he was accordingly summoned In the meantime hypodermic injections of morphine were given The temperature was subnormal and the pulse rate was from 120 to 130 On Mr Allingham's arrival operation was decided on

The anæsthetic was administered by Dr E Chittenden Bridges An incision was made in the median line from the ensiform cartilage to just above the umbilicus about five inches in length Immediately on opening the peritoneal cavity fluid welled up and, in short the abdomen was full of the contents of the intestine The stomach was carefully drawn out of the wound and examined both anteriorly and posteriorly but no perforation could be found It was notably dilated On further examination a large sloughing ulcer of about the size of a penny was discovered in the *duodenum, about two inches from the* pylorus *This* was carefully sutured The abdomen was thoroughly flushed with boiled water and as far as possible cleansed by repeated sponging The abdominal wound was then closed and a long gauze plug was left in the upper and lower parts of the wound, the abdomen being allowed to remain full of sterilised water with the object of diluting as far as possible any intestinal contents that might remain

The patient was in such a grave condition of collapse that although the question of performing gastro enterostomy was considered it was decided that it was impossible to perform it in his then condition One thirtieth of a grain of strychnine was injected during the operation The patient was put back to bed and brandy was injected hypodermically These hypoderms of brandy were repeated at intervals as occasion arose and nutrient enemata were given every four hours Very little pain followed the operation and the patient gradually rallied Nothing was given by the mouth for 36 hours when one teaspoonful of plasmon was cautiously administered every half hour A slight rigor occurred about 24 hours after the operation 48 hours after the drachm doses of plasmon were stopped as hiccough occurred, a turpentine enema was given, part of which was retained The enema was repeated on the 10th with some success Plasmon and brandy were recommenced on the 10th, two drachms being given every hour The patient was fairly comfortable and passed flatus freely On the 12th, six days after the operation, the plugs were removed under an anæsthetic During this time the pulse had varied between 112 and 140 and the temperature between 97° and 99 6° F On the 13th the temperature rose to 101° The feeding by the bowel was continued, also occasional hypoderms of strychnine and brandy were given The plasmon was increased to four drachms alternated with the same quantity of peptonised milk The condition had in all respects improved The stitches were removed on the 16th On the 19th hiccough recurred accompanied by a feeling of nausea and abdominal pain *Food was stopped Hæmatemesis recurred* with much pain and collapse Adrenalin in five minim doses was administered every hour, and for the collapse brandy and strychnine were [illegible] and a sixth of a grain of m [illegible] was kept going with nutri [illegible] made to give nourishment by the mouth for 48 hours, when plasmon and brandy, two drachms at a time, were given every hour The bowels were induced to act by hot water enemata and there was *evidence of old hæmorrhage in the actions* Raisin tea (two drachms at a time) was given alternately with plasmon On the 25th a thrombus formed in the left leg, which was greatly swollen In other respects the patient appeared to be making progress, feeling no discomfort after the plasmon and raisin tea, which were continued in slightly increased doses but never exceeding a total of 20 ounces in the 24 hours Occasionally whey and white of egg were given On May 4th hiccough again *occurred and on the 5th nausea*, vomiting, and hæmorrhage once more threatened to put an end to the patient's life Adrenalin was again given The hæmorrhage on this occasion was more copious than hitherto and the patient's condition seemed hopeless as in spite of the extreme care which had been exercised in feeding him it was quite clear that the stomach did not empty itself and that the ulcer was not healed On the 7th raisin tea was again given in two-drachm doses and on the 8th similar quantities of plasmon The temperature on the 6th sank from 100° at 2 A M to 96 6° at 6 P M The pulse was 110 As the patient was losing strength and becoming much emaciated it was felt hopeless to persevere with the present course of expectant treatment and the question of performing gastro enterostomy was raised Mr Allingham concurred in the opinion that nothing remained but to do this and on the 11th Dr Bridges again administered an anæsthetic and Mr Allingham performed posterior gastro-enterostomy

An incision was made parallel with, and to the left of, the original wound between five and six inches in length The stomach had greatly diminished in size since the first operation and the ulcer was quite shut off by adhesions and could not be seen The patient stood the operation well and from this time there was no further trouble Liquid food was commenced on May 13th and increased gradually By the 20th he was taking chicken broth, milk and barley water, Benger's food &c The stitches were removed on the 21st, *and within a fortnight of the second operation* he was taking solid food in fair quantities, and within three weeks he was quite convalescent There has been no further trouble at all

A CASE OF HÆMATOPORPHYRINURIA NOT DUE TO SULPHONAL.

BY G. LESTOOK THORNTON, M.A. CANTAB., M.R.C.P. LOND., M.R.C.S. ENG.

On July 13th of this year I was summoned to attend a man, aged 45 years, of good social standing and no occupation, who complained of griping pain in the abdomen, nausea, and slight diarrhœa. The patient's family history was good and there was nothing of ill omen in the account that he gave of his previous health. He appeared to have been in good health until July 8th, on which day he suffered from diarrhœa with abdominal discomfort. On the 9th the diarrhœa ceased and on the 10th he felt quite well. On the 11th he travelled to Bristol, returning to Exmouth on the 12th, and in the evening of this day he complained of headache which was followed in the night by slight sickness and diarrhœa, the last of these symptoms continuing until I saw him on the evening of the 13th.

The patient was a man above the average height and strongly built. He showed signs of a very nervous temperament. The temperature was 98° F. in the axilla (he had taken it himself in the morning and found it to be 100·5°). The pulse was 54 and of high tension quality. The tongue was moist and slightly coated all over with white fur. With the exception of an accentuated aortic second sound nothing abnormal was noted on examination of the chest. The abdomen moved freely with respiration and there was no marked distension. There was no evidence of enlargement of the liver or the spleen. There was slight tenderness over an area corresponding to the ascending and transverse portions of the colon. No motion had been reserved for my inspection but I learnt from the patient that there had been some eight or nine during the day and beyond the fact that little had been passed with each motion I could obtain no definite information respecting them. He was ordered a mixture containing subcarbonate of bismuth, bicarbonate of sodium, and salol, the last of which was prescribed in five-grain doses. The mixture was to be given every four hours and his diet was limited to milk.

I saw him on the morning of July 14th and found that there had been three motions during the night, which motions consisted chiefly of blood-stained mucus and bright blood. At this interview the patient expressed some alarm at the colour of the urine which he had passed during the night and on that morning. The specimen which had been reserved for my inspection had been passed directly into a clean utensil and there was no question of contamination in any way. The appearance was that of an average good port wine and a port wine, moreover, which had been carefully filtered, so absolutely free was the urine of any sediment and so intimately was the pigmentation a part of the fluid. On subsequent examination of a sample (which I centrifugalised) the results of the analysis were as follows. Amount in 24 hours less than normal; colour, port wine; reaction, feebly acid; specific gravity, 1028; albumin, slight cloudiness on heating but no resulting deposit; no reaction with nitric acid in the cold or with Esbach's solution; sugar, *nil*; microscopical examination of the very slight deposit showed the presence of a few uric acid and urate crystals; no blood cells were present. On treating the urine with freshly prepared ozonic ether and tincture of guaiacum no reaction was obtained, thus excluding the presence of hæmoglobin. The presence of pure blood had been previously negatived by centrifugalisation and examination of the deposit, and the result was further confirmed with the test just mentioned. Although I had no facility for making use of the further spectroscopic tests there could be no question but that the pigmentation was due to the presence of hæmatoporphyrin.

In seeking for the cause of this condition, that one to which it is most commonly ascribed could be put out of court, for the patient had neither taken sulphonal on his own account nor at my direction. On referring to the subject in Osler's "Theory and Practice of Medicine" I found the most obvious solution, for Osler states that 'hæmatoporphyrinuria has occurred in patients suffering from intestinal hæmorrhages. I could find no reference in the larger text-books on therapeutics to such an occurrence after the taking of salol, but in view of the uncertain action of this drug I omitted it from the prescription as an extreme precaution.

The further progress of this case was uneventful, the simple colitis with which the patient was evidently affected responding to appropriate treatment. On July 15th the urine had still a distinct port-wine colour. On the 16th the colour was that of rich orange. On the 17th the urine had the appearance of mere high pigmentation, whilst on the 18th there was nothing abnormal in this respect. Beyond occasional bloody mucus in the stools there had been no evidence of hæmorrhage on these days.

This case is of interest on account of the few recorded in which the condition has occurred independently of sulphonal administration. The literature on the subject is at the present time meagre. Halliburton[1] (writing on hæmatoporphyrin) states: "It occurs in certain invertebrate pigments and may also be found in certain forms of pathological urine. Even normal urine contains traces of it." Osler,[2] in his Text-book on Medicine, says that "hæmatoporphyrin occasionally occurs in the urine. It was first recognised by Hoppe-Seyler. Nencki and Seiler determined its exact formula and the former demonstrated that the only chemical difference between hæmatin and hæmatoporphyrin is that the latter is simply hæmatin free from iron. It has been found in the urine in pulmonary tuberculosis, pleurisy with effusion, acute rheumatism, lead poisoning, and intestinal hæmorrhages. This pigment has been found very frequently after the administration of sulphonal." Hutchison and Rainy[3] state that hæmatoporphyrin sometimes occurs in large amounts in the urine of patients who are taking sulphonal and that the occurrence is more common in females than in males. These authors also draw attention to the grave significance of the symptom when caused by sulphonal. Rose Bradford,[4] writing in Allbutt's "System of Medicine," mentions hæmatoporphyrin both amongst the normal and abnormal pigments of the urine. The same author assigned to Dr. A. E. Garrod the credit of having first discovered traces of it in normal urine. Rose Bradford also tells us that hæmatoporphyrin has been observed in rheumatic fever, Addison's disease, peritonitis, and cirrhosis of the liver. He also states that various drugs (not mentioned by name) have, in common with sulphonal, the property of producing this condition of the urine. Lastly, at a meeting of the Pathological Society of London held in March of this year[5] Dr. Garrod gave a survey of the few recorded cases of hæmatoporphyrinuria not due to sulphonal. Dr. Garrod referred briefly to 12 cases and drew a distinction between them and the very common ones where the increase above the normal amount of hæmatoporphyrin was not such as to affect materially the colour of the urine. In a large proportion of these 12 cases the condition was of long standing, in others there was occurrence at intervals, whilst in one instance paroxysmal hæmoglobinuria was simulated. In only two cases were the grave symptoms present which accompany hæmatoporphyrinuria due to sulphonal. As to the cause of this phenomenon Dr. Garrod considered that the evidence is in favour of perversion of hæmoglobin catabolism rather than that of excessive hæmolysis. He also mentioned the morbid changes met with in the liver in hæmatoporphyrinuria both when and when not associated with the taking of sulphonal.

In the case I have recorded the most obvious cause would be that a somewhat severe hæmorrhage had taken place high up in the colon, as there was never at any time tenderness over the sigmoid flexure and nothing abnormal could be detected on rectal examination. My case agrees with the majority of Dr. Garrod's 12 cases in that there were no grave symptoms present, but differs in that there was no history of the symptom having been previously present, at any rate in such a degree as to attract the attention of the patient.

The scant literature on the subject and the paucity of the few published cases of hæmatoporphyrinuria occurring unassociated with sulphonal seem to make it worth while to place this one on record.

Exmouth.

THE CHANNELS OF INFECTION IN TUBERCULOSIS IN CHILDHOOD

BY L KINGSFORD, M D EDIN, D P H CANTAB,
DEPUTY MEDICAL OFFICER OF HEALTH OF BRIGHTON

DURING the last few years, but more especially since the address of Professor Koch at the Tuberculosis Congress of 1901, this subject has aroused great interest and considerable discussion His statement that tuberculous milk is not a source of danger to the human subject has, speaking generally, met with strong opposition both in this country and abroad Indeed, some observers have recently gone to *the other extreme in contending that practically all cases of* tuberculosis at any age can be traced to the ingestion of tuberculous milk in infancy or childhood The majority of observers, however, steer a middle course and the weight of evidence seems at present to rest with them The question is a difficult as well as an important one and it is only when a large mass of evidence along the different lines of investigation has been accumulated and weighed that a definite and satisfactory conclusion can be arrived at Partly with this object I have analysed the post mortem records of 339 cases of tuberculosis in children of all ages up to 14 years, taken from the East London Hospital for Children, and I must express my indebtedness to Dr W P Branson, the pathologist at that institution, for allowing me to have access to these records The following table shows the ages at death of all the patients and the number at each age infected through the different channels

TABLE I —*Showing the Ages at Death of all the Patients and the Number at each Age infected through the Different Channels*

Ages.	No of cases	Primary infection			
		Thoracic.	Abdominal	Pharyngeal	Doubtful
Up to 6 months	14	12	0	1	1
6 to 12 ,	58	39	7	3	9
1 , 2 years	90	52	16	6	16
2 „ 3 „	51	30	16	0	5
3 , 4 ,	30	19	5	1	5
4 „ 5 „	27	18	6	0	3
5 „ 6 „	18	14	2	0	2
6 „ 7 „	14	9	5	0	0
7 „ 8 „	12	7	2	1	2
8 „ 9 „	4	2	1	0	1
9 „ 10 „	6	3	0	1	2
Over 10 years	9	4	4	0	1
Age not stated	6	3	0	0	3
Totals.	339	212	64	13	50

It will be noticed that 162, or 48 *per cent*, *occurred* during the first two years, and 270, or 80 per cent, during the first five years, whilst there is a steady decline in the proportion amongst older children This does not necessarily indicate a greater amount of tuberculosis in terms of children living under five years, though from our collateral knowledge there is reason to believe that this is so

The following are the recognised methods of infection (1) inhalation, (2) ingestion, (3) inoculation, and (4) placental, but for all practical purposes our attention may be confined to the first two, as the other methods are exceedingly rare I
settle on any part of
mouth to the alveol
tends to show that under ordinary conditions the inspired air is free from foreign particles by the time it reaches the larynx[1] On the other hand, dust inhalation experiments show that when foreign particles are present in great numbers they may be inhaled even into the alveoli, and this is seen too in cases of anthracosis and other dust diseases. It is possible, however, that the children of the poorer class, living as they do so frequently in close, badly ventilated, dirty, and tubercle infected dwellings, are subjected occasionally to the inhalation of large numbers of tubercle bacilli and so a repetition of the dust experiments may occur At any rate, 49 per cent of my cases were infected apparently through the mucous membrane of the trachea or larger bronchi Of the upper respiratory passages *the pharyngeal tonsils, the middle ear*, and the faucial tonsils have been shown to be sometimes the points of entry of the disease Bacilli passing through mucous membranes at any point are soon found to be present in the adjacent lymphatic glands, showing the course usually taken by the bacilli when invading the system In the case of the fauces or naso pharynx the cervical glands suffer and the tracheal, bronchial, or pulmonary glands when the bacilli enter through the mucous membrane of the trachea or bronchi

Ingested bacilli are liable to settle on any part of the alimentary tract from the mouth onwards The mouth, *fauces, and pharynx are thus common both to inhalation* and ingestion and infection through these parts would leave a doubt as to its sources The œsophagus is, except during swallowing, quite empty and thus food or foreign particles are only for a very short time in contact with its mucous membrane Tubercle of the œsophagus is extremely rare and when occurring is as likely to be due to infection through the blood stream as to food The stomach, also, is rarely tuberculous but the intestines not infrequently Bacilli passing through the intestines would be conveyed to *the mesenteric and sometimes other abdominal glands and* these glands are frequently tuberculous

The next point for consideration is the importance of tuberculosis of the lymphatic glands in children In over 90 per cent of my cases the lymphatic glands were obviously tuberculous, whilst in *68 per cent they were the primary* foci The great activity of the lymphatic system in early childhood and the rapidity with which the glands enlarge after some peripheral irritation, such as eczema, are matters of common knowledge It is not surprising, therefore, that they do not show any great powers of resistance against the tubercle bacillus, which, as Carr has shown,[2] usually invades the system primarily by the lymphatic channels, though it may be conveyed secondarily to lymphatic glands by means of the blood stream *This reasonable view has been taken, I* think, by all observers except so far as it applies to the tracheal and bronchial glands, and for the infection of these there are, as Pryce Jones[3] has pointed out at least five different methods suggested 1 Through the trachea and bronchi, the most natural suggestion 2 By the pharyngeal lymphatics In this case a continuous chain of caseous glands should extend down the neck as far as the thoracic inlet and the thoracic glands would be infected secondarily Nine of my cases showed this method of infection 3 Through the œsophageal mucous membrane As mentioned above, this must be very rare 4 From the intestinal mucous membrane[4] or mesenteric glands, either by three ways suggested by Woodhead or by the thoracic duct In the former case primary infection of the mesenteric glands is presupposed and in five cases I was able to trace this line of spread With regard to the thoracic duct, Ravenel[5] has suggested *that tubercle bacilli taken with the food might* pass through the intestinal mucous membrane and be carried through the mesenteric glands by the lymph flow directly to the thoracic duct He was led to this opinion by certain feeding experiments on animals, when a small proportion of the cases showed tuberculous lesions in the thorax alone Sidney Martin,[6] Baumgarten,[7] and others with similar experiments have not confirmed his observations, so that this line of infection must be considered rare The result of an infection through the thoracic duct should be miliary tubercles throughout the lungs and perhaps other organs with only secondary lesions in the bronchial glands 5 Infection by the blood stream must, if primary in these glands be very rare If, however as might be suggested the route is by the blood stream directly from the intestinal mucous membrane, miliary tubercles, first in the liver and then in the lungs, should result and the bronchial glands the lesions in the thorax and abdomen were too far advanced to give any clue as to the method of infection.

[3] Lubie [illegible] vol xv, 1902.

[6] Transactions of the Medical Society of London vol xvi

[7] Ueber Tuberkel w Tuberculose, [illegible]

No mention has been made of cases of inoculation as in tuberculous warts or in lupus. These cases almost always remain local and are of secondary importance in a paper of this nature. The same may be said of placental infection or congenital tuberculosis on account of its rarity. Such cases seldom are admitted into hospitals as they rarely live beyond the age of a few weeks.

In conclusion, if we regard the middle-ear cases as infected by inhalation, the tonsil cases as an alimentary infection, and the remaining pharyngeal cases as doubtful, since it was not certain whether the infection had entered by the tonsils or naso-pharyngeal adenoids, then inhalation would account for 216 cases, or 63·7 per cent., and ingestion for 65, or 19·1 per cent., the remaining 17 per cent. being of doubtful origin. So far, therefore, as can be judged from these methods of investigation the danger from inhalation far exceeds that from the ingestion of tuberculous material. With regard to the importance of tuberculous milk, however great the potential danger may be, the real danger is in many quarters greatly exaggerated, probably owing to the children not drinking the tuberculous milk of the virulence and in the quantity usually affirmed. Still, whether the danger has been exaggerated or not, the fact that nearly 20 per cent. of the cases of tubercle amongst children in the large towns in this country are primarily alimentary makes out a good *primâ facie* case against tuberculous milk, and I believe it will be shown that one of the chief differences between the conditions of life amongst children at home and abroad which could have any effect in predisposing to primary abdominal tubercle exists in the greater frequency of tuberculous milk in this country. But whilst attention is rightly being directed towards the restriction of the sale of tuberculous milk, it is chiefly to the improvements in the conditions of life—such as cleanliness, ventilation, disinfection, and better housing—that we must look for the diminution of tubercle amongst children.

Brighton.

SOME POINTS IN THE PREVENTION OF EPIDEMIC DIARRHŒA.

By J. T. C. NASH, M.D. Edin., D.P.H. Cantab.,
MEDICAL OFFICER OF HEALTH, SOUTHEND-ON-SEA.

Many adhere to what they term "the well-established fact" that "when the subsoil temperature at a depth of four feet below the surface reaches 56° F. diarrhœic affections become prevalent each summer." The observation was originally made by Dr. Ballard, but I have shown[1] that though the four-foot earth temperature at 56° and the advent of diarrhœa are frequently coincidental they are not always necessarily so. My own opinion is that the usual seasonal circumstances during July, August, and the first half of September are in favour of contamination of food (especially milk) firstly and chiefly by flies and secondly by dust. The warm weather favours the rapid multiplication of deleterious germs deposited by flies and dust. I am quite convinced from continued observations that the common housefly is the principal agent in carrying diarrhœa-causing bacteria to food. I have always found that the districts which have most diarrhœa are those which are most infested with flies, particularly if in the neighbourhood of refuse heaps, manure pits, stables, midden-privies, and similar collections of organic refuse, which serve as breeding places for flies as well as for the noxious germs which they carry thence to the food-supplies in adjoining houses and shops. When once a case of diarrhœa occurs during the fly season (particularly in poor neighbourhoods, where houses closely adjoin, where the hard-working mother of a family has so much to do that she does not always immediately remove soiled napkins, &c., but leaves them about exposed) it is easy to see how flies can readily spread infection to adjoining houses.

Where municipalities neglect to flush the streets properly, desiccated horse dung (as first suggested by Dr. F. J. Waldo) and other deleterious organic dust which is commingled with ordinary street dust must also play a part in the causation and spread of diarrhœa when gusts of wind blow such dust on to exposed food, but I am of opinion that the part played by dust is but small in comparison with that played by flies. I have no hesitation in asserting that the number of cases of epidemic diarrhœa occurring during any summer will be found to vary directly with the number of flies present in any given season. I am not alone in this opinion. Many medical officers of health and others have ascribed to the domestic fly some part in the spread of diarrhœa, but my opinion is that the fly is the chief factor in epidemic diarrhœa as the carrier of infection, just as the mosquito plays a similar rôle in connexion with malaria. This opinion is shared by Dr. Edward Blake who in his recent interesting work on "Colitis"[2] italicises this sentence: "The fly season is the diarrhœa season."

Where milk-supplies have been contaminated by careless milkers at the cowsheds the warm temperature of summer, *quâ* temperature, must play some part in the rapid multiplication of hurtful organisms. This no doubt accounts for the greater number of cases which occur independently of fly contamination. The essentials for putting a stop to the great waste of infant life every summer are: (1) Clean milk-supplies; (2) clean towns with well-organised systems of sewage removal, dust collection and disposal, and street watering; (3) clean homes, where sufficient domestic hygiene *prevails to understand the importance of clean utensils for* food, *the covering over of food to protect from dust and flies*, and personal habits of cleanliness; and (4) inhibition of fly life. This will largely depend on the previous requirements. Should any community enjoy the fulfilment of all these requirements I venture to think that that community will also enjoy a remarkable immunity from epidemic diarrhœa, no matter whether the four-foot earth thermometer registers 56° for the greater part of the summer or not.

In connexion with this matter I have recently had printed the following hints to householders in the hope of preventing much unnecessary diarrhœa.

Diarrhœa.

This disease is very dangerous and rapidly fatal in young infants. It is therefore necessary to know how to prevent it rather than to hope to cure it. Several causes contribute to this disease. Any or some or all of these causes may operate in a particular instance. It is important to know what they are and to take the necessary precautions to prevent all if possible. They are in one word—dirt. In more than one word they are: (1) unclean mill [illegible]
and bottles; (3) unclean hands; (4) [illegible]
air (from overcrowding, &c.); (6) un [illegible]

Diarrhœa is more common and fata [illegible] time. Why?

1. Because there are more flies, which settle on dirty refuse heaps, dirty closets, dirty napkins, &c., and then settle on the food or tumble into the baby's milk, or get into the open tin of condensed milk, or walk about the sugar.
2. Because there is more dust, which is blown in at the open window on to milk and other food left exposed.
3. Because germs are really very small microscopic plants, which, like nearly all other plants, grow best when the weather is warm.

Fortunately boiling will destroy nearly all germs. Therefore during the hot weather, to prevent young infants from getting diarrhœa from milk boil all milk directly it comes into the house. But this is not everything. If after milk is boiled it is put into a half-cleaned jug or cup or bottle, or is left exposed so that flies can settle on the margin or fall into it, it will rapidly become contaminated again. Therefore, after boiling always keep the milk in clean vessels and covered over with a clean cover. The milk should also be kept as cool as possible. A good plan is to stand the covered milk jug in a basin of cold water. A mother or nurse should always wash and dry her hands just before preparing the baby's meal. A large number of people in a room contaminate the air of the room and impart to it properties which will rapidly spoil milk. Therefore it is important not to allow several people to come into the kitchen or near the larder.

Every precaution should be taken to prevent flies settling on food and to destroy flies in the house. All animal and vegetable waste should be burned as soon as possible. If put into the dustbin or left about in the kitchen or larder they cause offensive smells and attract and breed flies. Cleanliness in every detail is the great preventive measure against diarrhœa.

When a case of diarrhœa occurs in a house great care should be taken to at once place soiled napkins, &c., in a disinfectant solution and to boil all infected articles as soon as practicable. If napkins, &c., are left exposed flies can settle on them and carry back infection to the baby or to other children in the same house or in neighbouring houses.

Another pamphlet is distributed which, among other matters, calls attention to the dangers of long-tube bottles, poor condensed milk, miscalled infant foods, &c., and gives simple directions for preparing milk for hand-fed infants according to age. Under present conditions of milk-supply the boiling of milk used for infant feeding is an unfortunate necessity, particularly during hot weather. Unless facilities exist for supplying pasteurised milk the simpler the processes recommended to the poor and ignorant the better. The pamphlet method of instruction has its limitations, but no doubt effects much good in some instances.

A CASE OF NEPHRITIS SIMULATING DIABETES INSIPIDUS

BY J BRUNTON BLAIKIE M D EDIN,
MARGARET STREET W
OR SICK CHILDREN

THE case described as diabetes insipidus by Dr A H Carter in THE LANCET of August 26th (p 588) has prompted me to narrate the following case which occurred in Sir Thomas Fraser's wards of the Royal Infirmary Edinburgh in the summer of 1897

The patient was a girl, aged 11 years who was admitted with the complaints of great thirst and the passing of large quantities of urine Her previous health beyond the fact that at the age of three years she had had jaundice and when six years old she had measles was stated to have been good There was no history of an attack of scarlet fever Ever since infancy she was said to have drunk large quantities of fluid, even when a baby her nurse noticed that she consumed much more milk than is usual in an infant of her age She was always thirsty and would drink any fluid to which she could get access if deprived of a sufficiency of water At times she was also exceedingly voracious For a few months previous to admission to hospital she had been getting rather weak and she was noticed to be languid and easily tired

On examination the patient was observed to be thin but not emaciated, she weighed 3 stones 1 pound The mouth was dry and the tongue was slightly furred The bowels were said to be usually constipated The circulatory system was apparently healthy the pulse tension was not increased nor was the vessel wall thickened The skin was rather dry and harsh Nothing abnormal was to be detected in the respiratory hæmopoietic or nervous systems The urine during the first ten days in hospital averaged 90 ounces, it was clear neutral or faintly acid of specific gravity from 1003 to 1006 and contained a faint trace of albumin, no tube casts were found The urea averaged 194 grains per diem

During the first two weeks she was in hospital she did not look seriously ill, but at the end of ten days it was observed that both the quantity of urine and the amount of urea passed began to diminish Four days later she complained of discomfort in the epigastrium, nothing abnormal could be discovered on examination but her general condition became more disturbed than could be accounted for by a simple stomach ache She was nervous and restless and the respiration began to become deep anxious, and jerky On the following day the bowels were very freely moved—the result of medicine—and she ceased to complain of the epigastric discomfort She however, now developed an acute pain over the left clavicle for which there was no apparent local cause Her anxiety and restlessness increased and she cried continuously The respiration had become even deeper and more jerky The tongue was furred, the pulse was 124 and bounding and the temperature was 97 4° F As the day advanced she became quieter but drowsy and weaker and complained of inability to swallow There was however no apparent paralysis During the last 24 hours she had passed about 40 ounces of urine By the following morning she had become unconscious, the right pupil was widely dilated and the left only partially so The pulse was weaker and the temperature was 97° There was commencing Cheyne Stokes respiration She gradually sank and died at 7 P M the same evening There was some twitching of the limbs before death

The post-mortem examination revealed no noteworthy morbid appearances except in the nervous and the urinary systems The brain substance was found to be œdematous, the grey matter of the cortex and the basal ganglia showed irregular patches of congestion The pons was studded throughout with numerous small hæmorrhages about one sixteenth of an inch in diameter These were of quite recent character, symmetrically arranged on the two sides and were more numerous in the middle of the pons Only a few small hæmorrhages were present in the lower part of the crura and one or two were seen in the upper part of the medulla The rest of the medulla showed general congestion of the grey matter but contained no hæmorrhages The following is the report on the kidneys "The left weighed two ounces and the right three ounces Both were extremely small, the capsule of each was adherent, the surface was somewhat irregular and showed extreme waxy pallor On section the cortex was enormously diminished especially in the left kidney, so as to constitute a mere line at places, with pyramidal cortex also diminished but to a less degree The whole kidney surface was of somewhat translucent yellowish white colour with only a few points and streaks of congestion at places There were numerous small cysts present both in the cortex and in the medulla, these were more numerous in the left than in the right kidney The Malpighian bodies appeared enlarged at places The condition was chronic nephritis with extreme contraction and atrophy probably following acute and subacute changes The extreme anæmia of the kidneys was very striking No waxy change was present

DEATH CERTIFICATION[1]

BY WILLIAM BERRY, F R C S IREL, D P H,
SENIOR HON RARY MEDICAL OFFICER TO THE ROYAL ALBERT EDWARD INFIRMARY WIGAN MEDICAL OFFICER F HEALTH OF THE COUNTY BOROUGH OF WIGAN

I AM presuming to address you on a subject which interests me personally as a medical officer of health and interests also the registrar of deaths who as a rule is not conversant with the medical terms used or with the pathology of disease

Death certification gets very scant attention from the various teachers in the medical curriculum so that when a young man is launched forth fully qualified unless he has had an opportunity during his vacation of seeing some general or out door dispensary practice he is somewhat at a loss to record in exact terms the cause of death in many of

of Diseases as published by the
s of London or if he will adopt
adopted by some authors in their text books on medicine he is somewhat helped The best synopsis is that found in Tanner's Index of Diseases The death certificate book does not help him much although you will find a list in the first few pages of the book and you will also find the following remarks It is highly desirable that medical practitioners should use in their certificates of death only those terms which are recognised by the Royal College of Physicians of London The cause of death should be stated precisely and briefly, English names for diseases being used in preference to their equivalents in other languages Vague terms such as *decline consumption tabes cachexia*, &c should be avoided and *hæmorrhage* should not be assigned as the cause of death without indication of its origin and probable cause *dropsy* should never be returned as the cause of death without particulars as to its probable origin—e g in disease of the heart liver or kidneys Now I agree with these remarks although the list given is not in strict accord with the pathology as dropsy is only a symptom Precise and brief sh

of the cause
should denote
term should be
dropsy as befo is only a symptom, hyperpyrexia is only a symptom

Whilst thinking out this paper I came across the following[2] It is from the annual report of the Registrar General for England and Wales for the year 1902

> *Inadequate Certification* —The deaths of 0,170 persons during 1902 were attributed to causes that are practically useless for purposes of classification A much larger number of deaths from indefinite causes would have appeared in the report but for the systematic inquiries

---

[1] Abstract of a paper read before the Wigan Medical Society on Sept. 1st, 1904

[2] Brit. Med Jour, August 20th, 1904 p 417

addressed to medical practitioners respecting deaths certified as due to dropsy, tumour, hæmorrhage, and certain other indefinite conditions. *In the course of the year* 4706 replies to these inquiries were received, resulting in most cases in a more precise classification of the causes of death. For example [illegible] alignant disease, 367 from tuberculous disease, [illegible] 153 from puerperal septic diseases, and 111 fror [illegible] ransferred to their proper headings, as a result c [illegible] ation so obtained.

I have taken somewhat haphazard from the list of returns for one year made to me by the registrar of deaths. These returns are also sent to the Registrar-General in London. The following are given as causes of death:—

1. Acute pneumonia.
2. Cardiac failure.

1. Scarlet fever 14 days.
2. Otitis media.

1. Bronchitis.
2. Cardiac failure.

1. Premature birth.
2. Asthenia.

1. Pneumonia two days.
2. Syncope.

1. Severe pressure during birth.

1. Acute mania.
2. Gangrene of both feet.

1. Broncho-pneumonia.
2. Cardiac failure.

1. Malignant tumour of colon 12 months.
2. Exhaustion.

1. Tubercular ulceration of stomach.
2. Exhaustion.

1. Enteritis.
2. Meningitis.

1. Bright's disease three months.
2. Hæmorrhage from brain one day.

1. Zymotic enteritis.
2. Collapse.

1. General tuberculosis.
2. Convulsions.

1. Severe burn on knee (left) nine months.
2. Disease of knee-joint probably tubercular.
3. Operation 24 days.
4. Pyæmia six days.

1. Senile decay.
2. Cerebral hæmorrhage.

1. Bronchitis with abscess one year probably tubercular.
2. Asthenia.

1. Cerebral hæmorrhage.
Coma.

1. Gangrene of foot.
2. Lymphangitis ten days.
3. Operation.
4. Exhaustion.

1. Scarlet fever and measles 20 days.
2. Bronchitis six days.

1. Teething.
2. Congestion of lungs.

1. Acute suppurative periostitis six days.
2. Exhaustion.

1. Valvular lesion of heart five and a half years.
2. Ascites 20 days.
3. Operation (tapping) two days.
4. Syncope.

1. Carcinoma breast (scirrhus).
2. Operation.
3. Recurrence.
4. Exhaustion.

1. Measles.
2. Pneumonia.
3. Cardiac failure.

1. Chronic nephritis.
2. Suppression of urine.

1. Chronic ovaritis.
2. Salpingitis 12 months.
3. Operation.
4. Syncope.

1. Acute congestive laryngitis five days.
2. Cyanosis.
3. Asphyxia.

1. Interstitial nephritis.
2. Embolism.
3. Heart failure.

1. Tubercular ulceration of intestines.
2. Diarrhœa.

1. Enlargement of liver.
2. Abdominal tumour.
3. Dropsy.
4. Heart failure.

Examples of Coroners' Verdicts.

Burns caused by ge [illegible]
Suicide [illegible]
Natural [illegible]
Burns b [illegible]
General break-up [illegible] juries while unloading on Lancashire and [illegible]
Burns by getting [illegible]
Self-neglect and alcohol.

You will see from this list that the certification is not *precise* and *brief* but is too full, and records in many instances symptoms for a disease. Tanner in his synopsis gives a good classification and one which meets all requirements.

[Mr. Berry here introduced an elaborate classification in tabular form which we are compelled to omit on account of its length. It contained 30 principal headings with a number of subdivisions under each.]

The Registrar's register is divided into columns and he has very little space for putting in the diseases. Although English is recommended by the Registrar-General as the simplest it is not always elegant or precise. The term "inflammation of the bowels" is unsightly and not precise and is much better expressed by "peritonitis" or "enteritis"; "inflammation of the lungs" also is better expressed by "pneumonia." Latin, I think, enables us to certify a cause of death precisely and briefly, and, again, it is not always wise to let the relatives know the cause of death in plain language; they are better pleased if the name of the disease has a jaw-breaking pronunciation and is a term not easily "understanded of the people." *Pew-monia* is a favourite disease from which many of our friends die, according to information supplied to us by relatives; the term certainly pleases the public.

In conclusion, I would suggest that a definite idea should be formed as to the filling up of the certificate and then the cause of death should be as brief as possible; if a primary disease is sufficient, then leave out the secondary one; for instance, "pneumonia acuta" is sufficient without putting "cardiac failure" or "syncope." Never give a third cause if possible.

P.S.—Since the above was written the following have been registered:—1. ——, aged three years: (1) acute toxæmia; (2) gastro-enteritis; (3) vomiting; (4) diarrhœa; (5) exhaustion; (6) collapse; (7) cardiac failure. 2. ——, aged seven months: (1) improper feeding; (2) rickets; (3) vomiting; (4) diarrhœa; (5) cardiac failure.

Wigan.

A NOTE ON THE PATHOLOGY OF LATERAL CURVATURE OF THE SPINE.

BY G. C. STEELE-PERKINS, M.D.

IT is not my intention to enter at all fully into the morbid anatomy and pathology of lateral curvature of the spine, as they have been fully dealt with by many authors. It will be sufficient to remark that in those cases in which there is a lateral deviation without rotation no structural changes are present; there are only weakness and want of development of the muscles. In cases in which there is lateral deviation with more or less rotation the changes present are dependent upon the amount of rotation that has taken place; in slight cases of this description little more than muscular wasting and relaxation of muscles are noticed, whereas in more advanced cases the changes include an alteration in the thickness of the bodies and intervertebral discs.

In severe cases the bodies of the vertebræ become very dense in structure on the side of the concavity and their cancellous tissue even becomes compact. The spinal muscles in severe and long-standing cases are often found to have undergone fatty degeneration and even fibroid changes are sometimes present. The thorax has its respiratory capacity much diminished and the viscera undergo alterations in their positions. The pelvis is more or less altered in shape according to the severity of the case and the lumbo-sacral angle trespasses either on the left or right of the cavity according as to whether the convexity of the curve in the lumbar region be to the one side or the other.

Any disease, constitutional or otherwise, which produces general debility and loss of stamina, gives rise to more or less difficulty in maintaining the erect position and the result is an increase in the normal antero-posterior convexity of the spine in the dorsal region—a condition which is known as kyphosis or stooping. This general want of muscular strength if associated with some determining factor causes a lateral deviation of the spine to occur, which when persistent and if more than to a limited degree, and accompanied as it is with a weakening of the spinal ligaments, must of necessity give rise to rotation of the bodies of the vertebræ. Where there is a general falling off in muscular power it is the spinal muscles that suffer more than any other part, as they have to maintain the body in the erect position. "Determining factors" may be instanced by the standing on one leg, writing in wrong attitudes, and various positions which have to be adopted when following certain occupations. The spinal muscles are prominent on the convex side of the curve and flattened on the side of the concavity. This is due to the transverse processes on the convex side being more prominent owing to the rotation of the bodies to that side, which of necessity causes the transverse processes to come backwards, and to the transverse processes on the concave side being less prominent owing to their being rotated forwards, added to which is the fact that the muscles on the concave side are weakened.

A curvature having taken place in one part of the spine, sooner or later a compensating curve will occur in another part. It is always an important point, as far as treatment is concerned, to decide which curve is primary and which secondary. The most common deformity met with is a curve in the dorsal region with the convexity to the right and a curve in the lumbar region with the convexity to the left. In many cases the dorsal is the primary and the lumbar the compensating or secondary curve, whilst in other cases the lumbar curve is primary and the dorsal secondary. For instance, if the determining factor be the excessive use of the right arm then the dorsal curvature would be primary and the lumbar secondary, whereas on the other hand if the determining factor be due to the fact that one leg is shorter than the other the lumbar curve will be primary and the dorsal curve secondary. In many cases it is very difficult to determine which of two curves is primary, nevertheless no trouble should be spared in endeavouring to form a correct diagnosis on the point. The importance of it lies in the fact that in treating the case it is the secondary curve that first disappears, although at the same time a reduction in the primary curve is taking place and it is the primary curve that is straightened last. We have first, therefore, to direct our main attention to the reduction of the secondary curve and when this has been rectified we can bring our energies to bear on the straightening of what remains of the primary curve. The cause of the deformity will in a large number of cases enable us to decide at once which is the primary curve. The primary curve is generally greater than the secondary, although sometimes the secondary curve is the greater of the two, in which case a third curve will often be found which is really compensatory to the second curve, and in the treatment of such a case the third curve must receive the greatest attention at first, then the second curve, and, finally, what then remains of the primary curve. A third curve may, of course, occur, and often does, without the secondary curve becoming greater than the primary curve, but nevertheless it is compensating to the secondary curve. The primary curve may be in the cervical, dorsal, or lumbar region; most usually it is in the dorsal region, but primary lumbar curves frequently occur, being caused by one leg being shorter than the other or a tilting of the pelvis to one side. It is to be noticed that a shortening of one leg does not necessarily, although it does usually, result in a lumbar curve with the convexity on the side of the shorter leg, as [illegible] onvexity of the [illegible] f the shortened [illegible] the fact remains. A compensating curve is naturally always on the opposite side to the curve which it compensates. A dorsal curve is not always compensated by a lumbar curve but sometimes by a curve lower down in the dorsal or else in the dorso-lumbar region.

HOSPITAL PRACTICE,

BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias, collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

ST. MARY'S HOSPITAL.

TWO CASES OF RICHTER'S HERNIA WITH PERFORATION AND PERITONITIS.

(Under the care of Mr. V. W. LOW.)

CASE 1.—A woman, aged 30 years, was admitted to St. Mary's Hospital on Feb. 3rd, 1904. In September, 1903, she had a doughy swelling in the right groin accompanied by pain; no impulse could be felt and there was neither vomiting nor constipation. The case was regarded as being one of inflammation of a crural gland and cleared up under local treatment. On Jan. 30th, 1904, the lump again appeared, accompanied by pain, and there was in addition some redness in Scarpa's triangle; no impulse could be felt on the patient coughing. The bowels did not act on this day. On the 31st there was some vomiting and the pain was worse; the bowels acted slightly. On Feb. 1st the vomiting ceased but the bowels did not act. On the 2nd the vomiting recurred in the evening and there was considerable pain in the region of the umbilicus. On the 3rd the pain became intense and the vomited matter was dark in colour and of a foul odour. There had been now no action of the bowels for three days in spite of repeated enemata and Dr. S. G. Felce, to whom Mr. Low is indebted for the history, sent her at once to St. Mary's Hospital.

On admission the woman appeared to be ill but was not collapsed. Her temperature was normal, her pulse was 96, and her respirations were 18. There was a soft, tender, non-expansile and irreducible swelling in the right groin in the position of a femoral hernia. The skin over the swelling was œdematous and red. The abdomen was slightly distended but the abdominal walls moved on respiration. There were no rigidity and only the slightest degree of tenderness.

At the ope[illegible] half an hour of her a[illegible] opening the sac of the hernia it was found to contain a quantity of foul pus and feculent material but no bowel. The abdomen was then opened in the middle line below the umbilicus and a condition of advanced general purulent peritonitis was discovered, the peritoneal cavity containing fluid fæces. Near the internal opening of the femoral canal was a coil of intestine about two inches above the ileo-cæcal junction, two-thirds of the lumen of which had been nipped by the opening of the femoral ring to form a Richter's hernia. The herniated portion was gangrenous and had perforated in two places. About four inches of intestine were excised, including the gangrenous patch, and two Paul's tubes were tied into the patent ends of the intestine. The abdominal cavity was thoroughly irrigated with hot saline solution and a glass drainage-tube was inserted into the pelvis. The patient appeared at first better after the operation but gradually sank and died 20 hours afterwards.

CASE 2.—A woman, aged 41 years, was admitted to St. Mary's Hospital on March 5th, 1904. She was in her usual health till Feb. 25th. She had previously suffered from pain in the right groin for two years and this pain had been accentuated during her last pregnancy, which terminated in August, 1903. No local swelling had ever been seen before the onset of the present illness. On the 25th the patient noticed a sudden pain in the right groin and she vomited. At the same time a swelling appeared in the groin. The pain was sharp and continuous and any food she took was immediately vomited. The pain continued and she was unable to do her work, though she still remained up and got about the house. The bowels were confined from the beginning of the attack. [illegible] passed. Enemata were [illegible] 28th she took to her bed, [illegible] severe and the pain intolerable. Her condition became steadily worse till she was admitted to hospital on March 5th. Her bowels had not been opened for eight days and for four days she had scarcely taken any food owing to the persistent vomiting.

On admission her pulse was 120, her respirations were 28, and her temperature was 97° F. There was no marked evidence of collapse and the woman was cheerful. The abdomen was flaccid and not in the least degree tender. There was a swelling in the position of a right femoral hernia which was *irreducible to slight taxis and non-expansile*; it was, however, tender and the overlying skin was slightly œdematou[illegible]ent fluid escaped but no bowel [illegible] was then opened in the middle [illegible]ral suppurative peritonitis was [illegible] filled with a purulent fluid similar to that which had escaped from the wound in the groin. The peritoneal surface of the intestines was injected and covered with flakes of yellow lymph, adjacent coils being adherent to each other. A coil of lower ileum was found, of which roughly half the circumference had evidently been strangulated, the strangulated portion still retaining the shape in which it had occupied the hernial sac. No obvious perforation was demonstrable but the herniated portion was covered with thick yellow recent lymph. The coil in which the strangulated area was situated was laid on the abdominal wall outside the peritoneal cavity, being fixed in position by a mesenteric stitch. The peritoneal cavity was thoroughly washed out with hot saline solution and a glass drainage-tube was placed in the pelvis. The wound in the groin was left open with a large rubber drainage-tube lead[illegible]y. On the next day the general [illegible] and the temperature was nor[illegible] in the evening. The temperature rose to 100° on the 8th but otherwise was never above 99°. On the 7th the end of intestine was covered with lymph and granulations and was found to be slowly recovering its normal shape, the pouch-like projection of the herniated portion gradually disappearing. The bowels were opened three times. On the 9th, under an anæsthetic, the coil of intestine was replaced and the peritoneal cavity, which still contained some straw-coloured serum and lymph, was again washed out with hot saline solution. The wound was partially closed and a glass pelvic drainage-tube was inserted. The patient's further progress towards recovery was uninterrupted but she remained in bed until April 14th owing to the length of time required by the wound in the groin to close. She left the hospital on April 22nd in good health.

Remarks by Mr. LOW.—These two cases, occurring within a few weeks of one another, present many features of similarity, the most striking being the insidious nature of the onset. In the first one it was only on the fourth day of the illness that the case was considered sufficiently serious to require operation, while in the second the woman got about the house for the first four days of her illness and it was not till the eighth day that she was brought to hospital. Neither of the women on admission appeared collapsed nor did their facial or general aspect suggest the serious nature of their illness. In neither case was there abdominal rigidity, the abdominal walls moved on respiration, and only in the case of the first woman was there the slightest abdominal tenderness, the absence of this in the case of the second being most marked. In both cases the strangulated portion of intestine had slipped away from the hernial sac and was found in the abdominal cavity a short distance from the ring. Perforation had occurred in both cases, but in the second the perforation had evidently become closed by adhesive lymph.

The question of treatment presented many difficulties. In each case excision with immediate suture would have been the ideal method. In the first case this would have involved replacing the newly sutured bowel into the infected peritoneal cavity, while the line of juncture would have been exposed to considerable strain owing to the previous obstruction, the coils of small intestine above the hernia being filled with foul liquid fæces and only a small quantity of this could be drained away at the time of the operation. Bearing all this in mind I determined to drain the intestines for a few days by means of a Paul's tube and then, if the patient lived, to suture the intestine at a second operation. In the second case the effects of the intestinal obstruction were not so obvious when the abdomen was opened and resection with immediate suture was therefore rendered more hopeful of success. But in this case there was still the objection of replacing the newly sutured intestine into the foul peritoneal cavity and there was also the possibility that resection might not be necessary. I therefore decided to withdraw the injured coil from the peritoneal cavity and if in the course of a few days it did not recover to perform a resection outside the peritoneal cavity. This, however, was fortunately rendered unnecessary.

Reviews and Notices of Books.

Manual of Practical Ophthalmology. By GEORGE A. BERRY, F.R.C.S. Edin., Senior Ophthalmic Surgeon Royal Infirmary, and Lecturer on Ophthalmology, University of Edinburgh. With 223 Illustrations. Edinburgh and London: Young J. Pentland. Sm. 8vo, pp. 570.

IN 1893 Mr. Berry brought out a second revised and enlarged edition of his work on the diseases of the eye. The present volume is based on that treatise and contains the results of his more matured experience. In so progressive a subject as ophthalmology, which is in intimate relation with every other branch of medical knowledge, 11 years embrace a period of great advance in the pathology and in the treatment of disease generally and those advances are faithfully reflected by Mr. Berry so far as they affect the eye. Although large portions of the volume are only a repetition of the last edition, scarcely a paragraph remains without some addition or alteration. To give an example in the treatment of detachment of the retina, in the older work he remarks (p. 223) that removal of the subretinal fluid by puncture through the sclera has often been tried but without any marked success. In the new volume he says: "I have obtained the best results by repeated punctures made with a Graefe's knife pushed through from one side of the eye to the other in the region of the detachment." This proceeding, he considers, is always worth trying in young people, though it is useless in complete detachment and in old people.

Again, the results of riper knowledge are rendered evident by such sentences as the following. "The various diseases of the cornea are in all respects the most important of the common diseases of the eye. They are for the most part cases in which not a little good can be done by proper and judicious treatment and in which much harm may result from wrong interference or neglect. Their importance lies in this coupled with the value to vision of the normal cornea. There are other parts of the eye which are, of course, equally valuable in this respect, but of few of them can it be said with equal justice that the treatment is often of great importance in influencing the consequences of the diseases by which they may be affected." These remarks are succeeded by others bearing on the subject of opacities and alterations of curvature, on which the student will do well to ponder. In regard to colour blindness, which is now so important in the testing of the vision of persons in many avocations of life, Mr. Berry only mentions Holmgren's wool test, which, though good in itself so far as it goes, should, if possible, be supplemented with coloured lights at distances of 200 or 300 yards, a procedure not difficult to carry out where several hundred railway officials or sailors have to be examined and reported on. Mr. Berry has prudently omitted or considerably reduced the chapters in his earlier work dealing with the optical principles and physics of the eye (notwithstanding that the amount of mathematical knowledge required to understand them could be easily acquired by any earnest student), because the book is really a manual for the young practitioner who has not, as a rule, the time to devote to such subjects.

Mr. Berry has little to add to his former account of sympathetic ophthalmia. The pathology of that affection is still obscure. The conclusions to be drawn from clinical observation are for the most part suggestive of microbic inoculation, for the disease almost invariably follows a perforation of the sclerotic or cornea, especially in the ciliary region. The injured, or exciting, eye long remains soft and tender in the neighbourhood of the wound, conditions that are favourable to absorption or entrance of micro-organisms, of which there are many forms in the conjunctival sac, into the lymphatic and vascular systems; and, lastly, a week or two usually elapses before sympathetic inflammation is excited in the sympathising eye, as though time were an element in the transmission. On the other hand, neither experimental nor bacteriological evidence has been obtained of the presence of any particular organism in either eye. Mr. Berry, however, remarks that this does not preclude the possibility of the transmission of toxins formed by the action of germs from the exciting eye into the sympathising eye. In regard to the treatment to be followed, whilst the general rules laid down in regard to the removal of the injured eye are sound, sufficient stress has hardly been laid on the value of complete rest of the eyes in a dark chamber for several days. An attack otherwise imminent may thus sometimes be warded off.

In speaking of the operations for the extraction of cataract Mr. Berry seems to prefer the combined method, that is, the method in which an iridectomy is performed, but he also approves in favourable cases of simple extraction. He insists, however, on making a large conjunctival flap, to which the objection may be raised that considerable hæmorrhage sometimes occurs which entering the anterior chamber, obscures the subsequent steps of the operation. We read with some surprise the statement made by Mr Berry that his own experience of Mules's operation has not been particularly encouraging. In a great many cases, he says, the glass ball seems to be expelled sooner or later by ulceration of the overlying tissues. Such results were *probably due to the introduction of too large a ball* in the anxiety to obtain a good and prominent bed or possibly in the too early insertion of the shell or artificial eye. Some weeks should be allowed to elapse before this is worn and then it should be worn only for a few hours at a time. Mr Berry seems to have been fortunate in his experience of Bowman's method of slitting up the canaliculus in cases of watery eye, as he states that "all that is necessary as a rule to cure the watery condition of the eye is to convert the canaliculus into an open rill." That this proceeding is sometimes successful is certain but the student should be warned that it is unwise to promise a cure, whilst it *may* happen that the patient is worse off after than before the operation. Large probes may sometimes be passed through the nasal duct with no consequent relief to the "watery eye." Slight cases are better left alone.

We commend the book to the student and the practitioner as one on which reliance can be placed and which may be consulted with advantage in any of the emergencies of ophthalmic practice.

By WILLIAM P SPRATLING
ndent of the Craig Colony for
With 16 Illustrations in the text
Philadelphia and New York
1904 Pp 522 Price 18s net

THE great progress made in the knowledge of epilepsy and its treatment during the past decade and a half and the fact that no complete treatise on the subject has appeared in the United States during the past 30 years were the chief reasons that led to the preparation of this volume by Dr Spratling. It includes definition and classification of the subject together with etiology diagnosis, prognosis, pathology psychological and medico legal aspects, and treatment. The author's work is the result of his experience as medical superintendent of the Craig Colony for Epileptics during a period of ten years.

In classification four types of epilepsy are recognised by the author—viz *grand mal petit mal* Jacksonian epilepsy, and psychic epilepsy. Etiologically epilepsy is regarded as a morbid or degenerative nervous affection dependent *on a similar condition in the parent* more frequently than on any other single cause while the author's statistics bear out the view that 80 per cent or more of all cases of epilepsy begin before the twentieth year. Methods of physical examination of patients are given in the early chapters. From a critical survey of the statistics of Great Britain France Belgium and the United States the incidence of epilepsy upon the general population is shown to be high but not nearly so high as that of insanity. One epileptic to 500 inhabitants is the estimate for the United States. The circumstances of age, sex, race, and occupation in their relation to epilepsy are dealt with in some detail. Heredity is made the subject of a specially interesting chapter which also sums up the other etiological factors.

The more strictly clinical part of the work occupies Chapters VI to X. The subjects dealt with are the different types of epileptic seizures, including rare forms such as psychic epilepsy and hystero epilepsy the status epilepticus, forms of epileptic aura, the casualties and sequelæ of fits, the post-epileptic state, and the diagnosis of epilepsy. The various clinical and diagnostic features are detailed with care and clearness. Much statistical knowledge is presented from the collected records of Craig Colony as to the frequency and character of many of the clinical phenomena. A chapter on Prognosis concludes the early half of the volume. The average age of onset of epilepsy, concludes Dr Spratling, is between ten and 20 *years and the majority of those who die through its effects* do so before middle age is reached.

The second half of the book is devoted to the pathology of epilepsy, to general treatment, including life in a farm colony and to medical treatment by drugs and other therapeutic measures. "In a disease in which [like epilepsy] etiology and pathology are obscure," says Dr Spratling "treatment must be more or less empirical." This applies even to the use of bromides. An account is also given of the recent work done in the serum treatment of epilepsy. The question of trephining in cases of epilepsy with focal indications of brain lesion is carefully discussed and the conclusion is drawn that the majority of those operated on experience no benefit, while about a fourth are somewhat benefited. Under antiseptic precautions little danger is to be feared from the operation itself. A fairly full account of the psychological and medico legal aspects of epilepsy concludes the second portion of the work.

Dr Spratling's work is written throughout in a clear and readable style. The plates and illustrations are useful and excellent the former would be hard to surpass. While not aiming at monographic completeness the work is a mine of information on the whole subject of epilepsy and its treatment and should be in the hands of every alienist and physician who has the care of epileptics in farm colonies and similar institutions.

A Compendium of Chemistry including General Inorganic and Organic Chemistry. By Dr CARL ARNOLD. Authorised translation from the eleventh enlarged and revised German edition by JOHN A MANDEL Sc D. New York John Wiley and Sons. London Chapman and Hall 1904. Pp 627. Price 15s.

THIS work has had a large circulation in Germany amongst students and professional chemists and its popularity there has induced Dr Mandel to undertake its translation into the English language. Dr Carl Arnold, the author is professor of chemistry in the Royal Veterinary School of Hanover and his success as a teacher is due to his faculty of clearly expounding both principles and facts. It is no small achievement to be able to deal with the whole of the principles and facts of chemistry in a comparatively small volume such as is the one before us. Yet this compendium a word by which the translator has rendered the word "Repetitorium" of the German text, comprises general inorganic and organic chemistry. Nor have modern advances escaped the author's attention. The work is divided into three parts and the first part on general chemistry is we venture to think the best example of the author's power as an exponent. The sections in this part on theory and on recent developments in physical chemistry are excellently clear. As an example may be quoted his explanation of the action of ions. "*The more completely an* electrolyte is associated" writes Dr Arnold, "the greater is its conductivity and its chemical activity since it is the free ions only which react. For example hydrogen chloride when dissolved in chloroform does not act on carbonates since in this case no dissociation of HCl is possible." The importance of the ion theory in physiological chemistry is also pointed out. As an example is quoted the poisonous action of certain metallic salts which is proportional to their dissociation and therefore alcoholic solutions of mercuric chloride or silver nitrate in which the salts are less dissociated than in their aqueous solutions are not fatal to anthrax bacilli. There can be little doubt that the theory of ions will have a very marked bearing on many points in medicine and we are therefore glad to find that this remarkable development of chemical theory is adequately treated. We pass over the second part of the work which deals with the chemistry of the inorganic elements. It may be said, however, that the author classes radium under the uranium compounds. Part III. deals with organic chemistry and here the author is just as clear as he is concise in the treatment of such subjects as constitution, substitution, stereoisomerism, and so on. Still, he finds space to deal with the terpine group, bitter principles, protenes, albuminoids, enzymes, and alkaloids. In short, the book is an excellent example of what a chemical text-book should be.

Le Soignage Médical et les Infirmières (Nursing and Nurses). By Dr. MARC BLATIN. Paris: J. B. Baillière et Fils. 1905. Pp. 276.

THIS little work, which is from the pen of a French physician of considerable experience in both hospital and private practice, is in effect a plea for general reform in all branches of nursing in France. The author reviews and contrasts the systems of training which obtain in his own country and in England, and it must be admitted that the conclusions at which he arrives are distinctly flattering to our own systems and to the *personnel* of the nursing staffs of our hospitals and public institutions. There are two factors which the author holds mainly responsible for the contrasts—so unfavourable to his own country—which can be drawn between the two national systems The first and most important of these is that while in France the nursing profession is recruited from an ignorant and humble class, in England the solid advantages of the occupation attract women who by birth and education are upon a higher social level. Although the author recognises that reforms are inevitable he believes that the change will only be effected slowly, for the reason that most of the large French hospitals are under central and Government control. Although perhaps all authorities will not agree with Dr. Blatin that centralisation of hospital administration is a barrier to progress, it must, indeed, be admitted that the *personnel* of the nursing staffs and the general standard of nursing are also very inferior in Poor-law municipal institutions in England as compared with those which are under the management of independent boards. Dr. Blatin insists that before most of the reforms which he suggests can be carried out in practice it will be necessary to educate the public to take an entirely different view of the status of the nurse. At the present moment she is regarded and treated simply as a domestic. It occurs to us that this view rather puts the cart before the horse. When the French nurse ceases to be a domestic in education and instincts she will assuredly receive the consideration to which her social status and improved education entitle her. We are certainly in greater agreement with the desirability of another step which Dr. Blatin considers necessary to obtain his object and that is that the comfort of nurses should be more closely considered in those institutions in which they receive their training. Among the many useful suggestions which Dr. Blatin makes for the satisfactory training of nurses, and especially of those who intend subsequently to engage in private nursing, is one that they should attend courses and lectures on invalid cookery; he says that such are provided in most of the English hospitals. We only wish that this were the case. Although this little book will have no particular interest for English readers we can quite imagine that its plea for reform will have an excellent effect in stimulating the somewhat slow-moving authorities of French hospitals to a sense of their responsibilities as far as the nursing of patients is concerned and to a sense of the possibilities which are open to them in the way of more systematic training of their staff and probationer nurses.

LIBRARY TABLE.

A Laboratory Manual of Organic Chemistry for Beginners. By Dr. A. F. HOLLEMAN. Translated from the Dutch by A. JAMIESON WALKER, Ph.D., B.A. New York: John Wiley and Sons; London: Chapman and Hall. 1904. Pp. 78. Price $1.—This laboratory manual is an appendix to the author's text-book of organic chemistry which was reviewed in THE LANCET of Nov. 21st, 1903. Its object may therefore be taken to be to give the student help when the opportunity arises for handling the compounds concerning which he is being instructed. The plan of the book is progressive. In the opening chapters the qualitative analysis of carbon compounds is described. Here simple methods for the detection of carbon hydrogen, nitrogen, sulphur, and the halogens are given. Next are described such laboratory methods as fractional distillation, determination of melting point and boiling point, extraction with solvents, and so on. The remainder of the book is devoted to the detection of organic compounds, including sections on the tests for alkaloids and the examination of albumins. The book affords an admirable laboratory companion to the author's text-book already referred to and an intelligent use of both would give the student a very excellent groundwork in organic chemistry.

Nature Teaching based upon the General Principles of Agriculture for the Use of Schools. By FRANCIS WATTS, B.Sc., F.I.C., and WILLIAM G. FREEMAN, B.Sc., A.R.C.S., F.L.S. London: John Murray. 1904. Pp. 193. Price 3*s.* 6*d.*—This little book was originally written for use in the West Indies with the intention of arranging the courses of study both in secondary and in primary schools, being employed as a text-book in the former, while in primary schools it is used by the teachers in preparing and formulating their teaching. As it was found so useful in the West Indies Mr. Watts (who is the Government analytical and agricultural chemist, Leeward Islands) has, with the assistance of Mr. Freeman, issued the present edition which has been written to meet the circumstances of British conditions. Elementary nature teaching admits a wide range of subjects and individuality plays an important part, but if good work is to be done it must be impressed on the teacher that the pupils must do things for themselves. For this reason but few illustrations are used in the book lest the pupils, seeing how things appear in the illustrations, may be tempted to shirk the effort of seeing the natural objects for themselves. In the appendix suitable courses of work are indicated according to the time of year at which the work is begun. In connexion with school gardening it is recommended that the elements of a simple drill should be introduced into the outdoor work and that in the working plots themselves the work should be carried out in a similar manner to that of a laboratory. The authors lay stress on the instruction that in all work drawing, measuring, and weighing should be insisted on. The book is divided into nine chapters which treat successively of the seed, the root, the stem, the leaf, the soil, of plant food and manures, of flowers and fruits, of weeds, and of the animal pests of plants. The chapter on Plant Food and Manures is excellently arranged and most instructive and the one on Animal Pests of Plants is very practical. When speaking of the remedies against damage to crops by injurious insects the authors write that "full directions concerning the use of many of these [insecticides] are to be found in the excellent leaflets of the Board of

Agriculture." Perhaps the information contained in these leaflets might with advantage have been included in this volume. The book is very simple and very practical and may be of great use if adopted in schools in this country.

Radium and other Radio-active Elements. By LEONARD A. LEVY and HERBERT G. WILLIS. London: Percival Marshall and Co. 1904. Pp. 105. Price 2*s.* 6*d.*—This little work is described as a popular account of radium and other radio-active elements treated experimentally and the authors have evidently taken pains to collect the latest information upon the subject. Setting out with an excellent object in view they have succeeded in putting together some valuable material, though occasionally their descriptions are wanting in clearness and a want of order is noticeable in the presentation of the facts. No apology need have been offered, we think, for the statement that the various theories of the sources of the radiation have received no attempt at explanation. A completely satisfactory explanation is not yet forthcoming even from the great masters. The merit of this little book, however, is its experimental character, although, unfortunately, the price of radium salts is calculated to deter many experimentalists. The authors have allowed themselves here and there to lapse into loose statements of which the following is an example: "The last decade has witnessed discoveries which have rendered possible the photography of the bones of a living being." The achievements of the x rays are wonderful but after all they merely effect the photography of shadows. If a telegraph pole were interposed between the sun and the sensitised screen the record would be the shadow of the pole and not a photograph of the pole itself. A photograph of the bones of a living being, as, for instance, of the skeleton, is a different thing from the impressions given on the sensitised plate by the shadows of the bones cast by the x rays.

A Guide to Medical Officers on Field Service, more especially Civilian Medical Officers and Junior Officers of the Royal Army Medical Corps. By Major J. S. EDYE, R.A.M.C. (Gale and Polden's Military Series.) Aldershot: Gale and Polden, Limited. 1904. Pp. 35. Price 1*s.* net.—The nature and object of this little publication are correctly and sufficiently set forth in its title. It embodies a great deal of information in a highly compressed form on all those official details and matters which come before a medical officer in the course of his duties and with which he has to be more or less acquainted in order to deal with them promptly and successfully when on field service. In glancing over its pages the reader will be surprised at the number and variety of duties of a quasi-military character which fall to the lot of an army medical officer to undertake or to know something about. On all these points this little book, it seems to us, supplies quite the sort of information that is required and in the most concise and accessible form practicable.

£300 per annum from 30 Acres; or, a Modern Bee Farm and its Economic Management. By S. SIMMINS. London: Woodford, Fawcett, and Co. 1904. Pp. xii.-405. Price 5*s.*—In placing this work before the reader Mr. Simmins says that it is his intention to adhere strictly to the science of practical bee-keeping. With few exceptions the instructions contained in the book are confined to the author's own experience which has extended over 30 years of close observation. He places the management of bees before the novice and those who wish to become bee-keepers in as clear and straightforward a manner as possible; simple matters are therefore gone into at length that the learner may profit by the author's own early experiences. At the same time he expresses a hope that the expert will find some things in the volume not known before to the bee-world. While there is no fortune to be made by bee-keeping it is a light and pleasant occupation and all may gain health and pleasure in following the study of one of the most remarkable creatures in the insect world. "The man who finds himself adapted to the undertaking may safely invest his money and be assured of obtaining better returns than very many other occupations offer at the present day." The author endeavours to show how a minimum profit of £300 per annum may be secured from 30 acres of grassland by making the most of everything that can be worked upon it, so that one branch of agriculture may help another. If the season is unfavourable for one item it is often even more suitable for some other of the several occupations carried out upon the farm of moderate dimensions. Work in some established apiary for two years is recommended to the would-be bee-keeper. Mr. Simmins's manual is well written, thoroughly practical, and a real guide to his subject. The work is fully illustrated.

JOURNALS AND MAGAZINES.

The Practitioner.—An excellent article by Dr. F. W. Mott opens the number of this magazine for the present month (September). Dr. Mott writes upon tremors, giving a clear classification and some capital graphic reproductions of tremor due to various organic diseases and to poisoning. Another article dealing with nervous disorder is supplied by Dr. W. L. Ascherson who discusses the distinctions between hysteria and neurasthenia and their association with other diseases. He gives cases illustrative of his reasoning and his article can be read with pleasure. Mr. P. J. Freyer continues his contribution on enucleation of the prostate, the illustrative plates being particularly good. The journal includes also contributions from Dr. S. Vere Pearson on Tuberculosis in Early Childhood, from Mr. J. Jackson Clarke on Paralytic Deformities, and from Dr. J. Blumfeld on Anæsthetics.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., with the coöperation of ADAM SEDGWICK, F.R.S.; W. F. R. WELDON, F.R.S.; and SYDNEY J. HICKSON, F.R.S. With lithographic plates and engravings on wood. London: J. and A. Churchill. Vol. XLVIII. Part II., September, 1904. Price 10*s.*—This number contains: 1. A long and important memoir by Professor Lankester on the Structure and Classification of the Arachnida, which is a reprint of his essay on this subject published in the tenth edition of the "Encyclopædia Britannica." It is illustrated by many woodcuts. 2. Some New Species of the Genus Phreodrilus, by W. Blaxland Benham, D.Sc. This genus is one of the oligochætous worms. Three species of phreodrilus are here described, which the author names Phreodrilus lacustris, Beddardi, and Mauiensis. They were all obtained from the lakes of New Zealand. The article is accompanied by three plates which give the details of the anatomy of these worms. 3. A New Species of the Genus Haplotaxis with some remarks on the Genital Ducts in the Oligochæta, by W. Blaxland Benham, D.Sc., with three plates. 4. The Œstrous Cycle in the Common Ferret, by Francis H. A. Marshall, D.Sc., with three plates. Dr. Marshall finds that the female ferret is monœstrous but many have one, two, or three sexual seasons within a year; the "heat" periods are usually restricted to the spring and summer months, the autumn and winter being occupied by a prolonged anœstrum. 5. Two New Forms of Choniostomatidæ, which are Copepoda parasitic on Crustacea, Malacostraca, and Ostracoda, by H. J. Hansen, D.Sc., of Copenhagen, with a plate.

THE SEWERAGE OF BOVEY TRACEY (DEVON).—At Bovey Tracey, on Sept. 14th, Colonel A. Durnford, on behalf of the Local Government Board, held an inquiry into the application of the Newton Abbot rural district council to borrow £7000 for sewerage and sewage disposal for Bovey Tracey.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 24, 1904.

Motor Vehicles and the Public Roads.

LETTERS to our contemporary the *Times* are justly regarded as indications of current opinion on the part of the British public. The text of many of these letters just now is the dangers and nuisances caused by motor-cars. We are not concerned with these actual letters, though it is impossible to avoid the conclusion that the manner in which the case has been stated against the motor-cars is more dignified, sympathetic, and considerate than the manner of the other side. The question is one full of minute difficulties and demands careful and judicial consideration on the part of the medical profession for there is no section of the community which is more concerned in the safety and ease of travel by road. Moreover, there is no class of men who will, within the near future, probably use motor-cars in their daily work to the same extent. We should not therefore allow our minds to be prejudiced unduly by the inconveniences and the dangers of the present. But nevertheless there is no class of educated men so well able to realise that the stern indictment drawn against motor-car drivers by Dr. SOPHIA JEX-BLAKE and others carries a true bill. To have driven with a medical man in country practice in parts of the home counties this summer is to have learned in a few days that the present use of the roads by motorists is dangerous and selfish. There are no better judges of such a question than country practitioners; they live on the roads, they drive seasoned horses not given to "nerves," they are from sheer practice good whips, and they are men whose daily life and work teach them consideration for others. There is no question that the allegations made against motor-cars have grave foundations. The properly trained driver or owner, particularly one who has had previous experience of the roads in charge of horses, gives no ground for offence, but the half-trained amateur and the reckless professional chauffeur do things which astonish and appal those who meet them. We have been shown by-lanes so narrow that in many parts two vehicles cannot pass and so winding that 200 yards are rarely visible ahead along which a racing Napier has been run for a dozen miles at a speed which distressed its occupants; we have seen a hill so steep that no local driver would permit his horse to trot down it but down which a four-cylinder Panhard car was launched at such a speed that two tyres burst at the bottom in attempting to round a corner and a disaster as appalling as that which recently occurred near Wicklow was averted only by mere chance. The excuse offered is that the driver did not know that the hill was so steep and that there was a corner at the bottom. The navigator of a valuable steam launch does not force it up a backwater of the Thames in ignorance of what may be in front but owners of costly cars, having neither maps nor knowledge of the country, rush them through narrow hilly lanes and run them at 15 miles an hour through small towns and villages along the narrowest roads, ignorant of the gradients and careless of the corners. We noticed the other day the track of a big car which we had just met and which had run through a tortuous line of streets and roads in a small town, taking almost every corner on the wrong side.

It is no exaggeration to say that the amenities of road travel in the home counties are being totally destroyed. There is no pleasure in riding a hack when the fate which recently nearly overtook Sir EDWARD BRADFORD (a fine horseman, we believe) may be coming on us at every corner. No girl home from school can ride her pony on Saturdays in Kent or Surrey now, for most motorists do not even know the proper side on which to pass a led horse. Few drivers of cars seem to be aware that it is not good manners to rush past another vehicle at top speed and that to change gear in the clumsy way in which so many drivers do change gear alongside a carriage is as offensive as it would be to shout at or to lash the horses of a passing vehicle. The slaughter of dogs in village streets is most callous and discreditable; our readers in small country towns and villages, since they dwell usually in the main street, need no reminders. They will appreciate also that all their front windows must be shut on Saturdays and Sundays because of the dust, that the hooter and the grinding change of gearing make Sunday afternoons hideous, while to step off the curb in front of the house without a glance each way along the street is as safe as to cross the metals at Finsbury Park. The accidents to life and limb, the widespread dangers to children, bicyclists, and old and infirm people, are all due to lack of consideration. There is no excuse for it for the average motorist is a man of leisure when on his car; moreover, the modern car is capable of great "flexibility" of speed and its pace can be reduced by a touch, but many drivers will neither lower their gear nor shut their throttles: they run ahead and blare upon their hooters. The two worst offences on the road are the maintenance of high speed in the centre of the track until close to an approaching horse and keeping the wrong side at corners. Horses may be trained to motor-cars for years but to run a large powerful car straight at another vehicle at a speed of over ten miles an hour in a narrow road and to deflect it at the last minute is more than most horses care about; a horse knows nothing about the subtleties of steering gear and sometimes even the steadiest will turn. To run corners on the wrong side at any speed is no less than a crime, since it is rarely possible in the narrow hedge-bordered roads of England to see sufficiently ahead to avert the serious accidents to children and animals which occur every week. We write in full knowledge of the value of modern steering gear and of the control afforded by clutches and clutch-coupled brakes but we are unpleasantly cognisant also of the laws of momentum and the working experiments instituted by the Automobile Club in the sudden arrest of heavy cars running at high speeds. The vast majority of these "accidents" are preventable and should be prevented. A better sense of responsibility in driving motor cars than has hitherto existed should be established. The legislation of last year is a complete failure. To follow the cases reported in the police courts is to realise that the punishment for offences is in no way deterrent, that too much stress is laid on the actual pace of locomotion and too little on the exigencies of the roads in use, while no attempt has been made by local authorities to enforce the provisions of the Act of 1903 which empowers county councils to limit speed within any areas or "places" which they may select, subject to the ratification by the Local Government Board of their restrictions.

We write not only on behalf of the general public who have to use the roads but also in the interests of motor cars; medical men use them largely now and will use them more largely after the extremely satisfactory trials of small cars[1] which the profession has been recently watching with much interest. If the conduct of motorists is such as to create a deep feeling against them which will be reflected in the actions of the county councils, limitations on the use of by-roads may be imposed which will be irksome to motorists in general, but which will be peculiarly prejudicial to the use of horseless vehicles by the class of professional men who need them most and who will unquestionably be valuable customers to the automobile industry in the near future. There are a large number of excellent journals devoted to motor cars but it is to be regretted that they do not seem to employ the influence which undoubtedly they possess to train the neophytes of motoring in the important items of careful and considerate driving. One well known manual, which has reached a third edition, has a full page illustration of "how to take a corner"—namely, on the wrong side of the road. It is true that the letterpress contains instructions stating when the illustration should not apply but the picture is far more obvious than the letterpress and has doubtless had regrettable results. One of the best periodicals contained in the spring of 1903 instructions, with diagrams, for getting the shortest line of travel on a winding road which involves for the better maintenance of equilibrium round curves the cutting of corners on the wrong side of the road. Both tutors and pupils think but of the speed and learn only the lesson of safety at the expense of disaster. All this must be changed and then the motor car will take its place as an unobjectionable as well as a most useful, means of locomotion.

The Practical Teaching of Gynæcology.

THE great strides which the art and science of gynæcology have made in the last few years have much increased its importance as one of the subjects of the medical curriculum. The standard of knowledge required of the student is now much higher than it was and the examinations are correspondingly more difficult. *Pari passu* with the development of the subject the teaching no doubt has improved but there is still much to be done in this direction. It may well be said that the two subjects of the medical curriculum which are most inadequately taught from the practical point of view at the present time are midwifery and gynæcology. Nor is the reason for this far to seek. It lies in the difficulties which surround the practical teaching of these two subjects—difficulties which in this country at any rate very little attempt has been made to overcome. There is perhaps no subject in the whole range of the student's career in which clinical teaching is of such importance, while the difficulties surrounding the proper carrying out of such teaching and the adequate examination of cases of pelvic disease are very considerable indeed. If the student requires constant practice to enable him to examine a case of heart or lung disease properly and systematically, how much more does he require such practice in the bimanual examination of the female pelvic organs? Yet from the very nature of the class of case it is often impossible for a student, no matter how energetic he may be or how keenly he may seize the opportunities afforded him, to become really expert in such examinations. The number that can examine any one case is strictly limited and the opportunities are correspondingly few. In our experience men are often loth to examine the patients and require constant urging to make them seize all the opportunities that are afforded them, nor is this frame of mind to be wondered at. Many of the gynæcological out-patient departments in our large general hospitals are flooded with a number of cases of no value from the teaching point of view and the time of the out patient physician is only too often taken up with such cases with the result that his opportunity for teaching is markedly curtailed.

It is a disheartening fact that there is no provision for any student who wishes to make a specialty of gynæcology to pursue his studies in London. It is true that if he has the time he can sometimes obtain a clinical assistantship at one of the special hospitals, but even there he is left more or less to his own devices, while of proper post-graduate teaching with an opportunity of carrying out a large number of pelvic examinations there is no provision at all. Constantly have we had to advise a student wishing to obtain a special course of instruction in gynæcology to go abroad to one of the foreign clinics. This is a condition of things which should not exist in the largest city in the world. It is the more to be deplored because the student sometimes in these circumstances must enter on his professional career without a sufficient amount of practical training to enable him to say with certainty whether the pelvic organs in any patient are normal or not. It must be confessed that the difficulties in the way of ensuring that every student shall be as competent to examine the pelvic organs as he is to examine the chest are very great. That they are not insuperable in the case of a small number of candidates for an examination is shown by the fact that at the last London M.D. examination in obstetric medicine arrangements were actually made by which a practical examination in gynæcology was conducted satisfactorily.

It will only be when the various examining bodies make a move in this direction that we shall see any marked improvement. With the increased tendency to treat so many of the diseases of women by operation the importance of accurate diagnosis becomes greater and greater. The representatives of provincial schools, have also expressed their intention to join the party. It is expected that altogether our visitors from France will number from 130 to 150 and we are certain that the English medical profession, especially those resident in London, will exert themselves to the utmost to render this visit useful, pleasurable, and successful in every way. Our guests will be entertained at dinner on Oct. 12th at the Hôtel Cecil and we have no doubt that a large number of English medical men will desire to be present to welcome and to honour them. Any further information can be obtained from Dr. Dawson Williams, 2, Agar-street, Strand, W.C., or Dr. W. Jobson Horne, 27, New Cavendish-street, W., the secretaries of the English Executive Committee.

---

[1] An account of these trials was given in THE LANCET of Sept. 10th, p. 799 and they are referred to also in another column of our present number.

"CELSUS REDIVIVUS."

ONE of our Italian correspondents writes: "Ciceronian in style, Hippocratean in method, the master work of Celsus once more appeals to his compatriots in the carefully constituted text and faithful rendering of Dr. Angiolo Del Lungo. Hitherto the 'Roman Hippocrates' has fared but indifferently at the hands of Italian translators. The Abbé Francesco Ranieri Chiari of Pisa, whose version saw the light at Venice in 1747, had slender qualifications for the work and seems, indeed, to have set himself the task of furnishing posterity with an object lesson in eighteenth century scholarship and style, the former characteristically loose, the latter characteristically affected. 90 years elapsed before another attempt in the same field was undertaken, this time with superior equipment in learning and literature, its author being Giuseppe Del Chiappa, a Tuscan by birth, and, like Chiari, an ecclesiastic by profession. Having qualified in medicine at the University of Pavia, in which he rose to be clinical lecturer, Del Chiappa acquitted himself of his task with some credit though leaving not a little to be desired in ease and elegance. His translation held the field for a quarter of a century till it was superseded by that of Salvatore di Renzi of Naples, whose monumental edition of Celsus is only less honourable to Italian medicine than his work on the 'Scuola Salernitana,' a mine of information on one of the most interesting episodes in medical history. Northern and Southern Italy having each tried its hand on reproducing the Roman classic it remained for Central Italy to bear away the palm in all the requisites of such an undertaking, and now we have in Del Lungo's text and translation as near an approach to the form and the charm of the original as life-long study and congenial gifts could make it. A Tuscan practitioner of many years' standing whose recreation after a laborious season was medical literature from Hippocrates downwards, Del Lungo left no resource untried for the elucidation and reproduction of his favourite author, the only part of his work which he was unable to perform being the revising of it in proof. This has been executed with adequate skill and pious care by his son Isidoro Del Lungo, who has had the competent aid of Professor Pietro Stromboli in a line-by-line comparison of the translation with the text and of Professor Enrico Rostagno of the Laurentian Library in a fresh collation of the Celsian manuscripts contained in that literary treasure-house. The result is before us in a compact and clearly printed octavo from the publishing firm of G. C. Sansoni of Florence, and its portability seems specially designed to render it—what it was to the translator—a companion equally pleasant and profitable on a professional man's holiday. A preliminary essay on 'Celsus and Roman Medicine' forms an illuminating introduction to the treatise itself, and from the finely moulded periods in the choicest Italian the reader is prepared for his encounter with an author possessed, *si quis alius*, of what the late Professor William Stokes of Dublin used to require in every votary of the healing art—the 'mens medica.' Here we are reminded of the substantial contributions made to therapeutic resource by the 'Roman Hippocrates,' who, according to Morgagni, was the first to recommend 'clisteri enutrienti' and whose suggestions for the relief of ascites have in Germany by Brunninghausen and in Italy by Pietro Betti been practised with the success that rewarded their originator. Here we find the history of 'anaplastic surgery,' how Celsus, who first makes mention of it, inspired the Sicilian operators, Branca, father and son, to revive it at the close of the fifteenth century till subsequent practice brought it to perfection through the Calabrian Vianeo to the great Bolognese surgeon, Tagliacozzi, called by his pupil Giambatista Cortesi, 'il legislatore ed il perfezionatore dell' arte plastica chirurgica.' And so through numerous resuscitations of 'wisdom old but new,' Del Lungo conducts us to the *quæstio vexata* of whether Celsus was a practitioner or consultant by profession, or merely the patrician amateur who acquired and practised the healing art much as the elder Cato did, in tending the slaves or *personnel* attached to his estate. Del Lungo's verdict is unreservedly for the former hypothesis, that Celsus was really a professional man, an illustrious member of the calling which the great Cæsar was the first to admit to the rights of Roman citizenship. But enough has been said to draw the reader's attention to what has been justly called 'the event of the year in Italian medico-historian literature'—an event which owes its significance not only to the transcendent merits of the classic as introduced, edited, and translated, but also to the filial care with which the posthumous work has been made accessible to the public by Signor Isidoro Del Lungo, himself an ornament of Italian literature, as witness (*inter alia*) his great edition of the mediæval Latin poet Pontanus."

HOSPITAL ABUSE.

THE question of hospital abuse has once again been brought prominently to the fore in the lay press. This is largely due to a correspondence which has recently taken place between the house committee of the London Hospital and the East-end Medical Association. The association maintained that the hospital authorities were treating as in- and out-patients individuals who had no just claim to take advantage of a charitable institution. The house committee expressed entire sympathy with the local practitioners and while realising that the matter was a difficult one to deal with drew up certain regulations with the view of checking any abuse. The principal clauses set forth in these proposed regulations are to the effect that the addresses of all patients will be taken and the books will be open to the inspection of any local practitioner. The local practitioners will also be invited to visit the out-patient department and if they recognise any patient known as being unsuitable for hospital treatment they will be able to communicate with the secretary. It is also announced that the committee is in communication with the Charity Organisation Society; it is hoped that this society will be able to advise the hospital as to the best means for inquiring about patients, while the hospital is willing to pay £100 per annum to the society for an almoner to be stationed in the receiving rooms. Finally, it is stated that the secretary has made arrangements to visit every patient admitted to the hospital on the day after arrival and if it is found that the patient is not of the class for which the institution is intended he or she is to be discharged and asked to give a donation for the time during which the patient remains in the hospital. The question of hospital abuse bristles with difficulties. Without expressing any definite opinion as to whether or not the proposals made by the house committee of the London Hospital are likely to aid in the solution of the trouble we feel quite certain that they were framed with every good intention and with a sincere desire to prevent injury being done to the practitioners of the neighbourhood Closely connected with the subject of hospital abuse is the proposal to admit patients into the hospitals on payment of small fees We have received from a correspondent a copy of a motion passed at the annual meeting of the governors of the Dorset County Hospital The resolution runs thus —

> [illegible] patients requiring surgical
> [illegible] or part of the cost of such
> [illegible] on the recommendation of
> [illegible] ample accommodation and
> [illegible] require assistance

Such cases will be admitted under the care of one of the honorary medical staff Such a rule would seem to safeguard any attempt to abuse the charity and to supply aid to a class of patient who is really in need of it There are many individuals who cannot conscientiously enter a charitable institution and yet cannot afford to pay the expenses which are entailed by a serious operation

MEDICAL FEES AT INQUESTS

AT a recent inquest at Edmonton the medical man who had attended the deceased had refused his certificate as to the cause of death on the ground that he had not attended during the two days preceding death and was summoned by the coroner as a witness In the course of his evidence he was questioned by the coroner as to his treatment of the deceased and refused to answer the questions thus put on the ground that the treatment used was the business of the medical man and not of the coroner, whose only duty was to ascertain the cause of death, as to which the witness had stated his opinion The coroner accordingly adjourned the inquiry and ordered another medical man to make a post-mortem examination At the adjourned inquest the second medical man gave evidence assigning a different cause of death from that given by the first and the jury adopted his view in their verdict, adding a rider to the effect that the first medical man was deserving of censure for the manner in which he had given his evidence at the first inquiry The coroner accordingly addressed the first medical witness, endorsing the view taken by the jury, and upon being applied to by him for his fee refused it To this the witness replied by a threat of legal proceedings which the coroner told him he was welcome to take Whether such legal proceedings have in fact been commenced we are not aware but if they are they will no doubt result in a statement of the coroner's powers in such matters The section of the Coroners Act of 1887 dealing with the fees of medical witnesses does so in the following manner ‘A legally qualified medical practitioner who has attended at a coroner's inquest in obedience to a summons of a coroner under this Act shall be entitled to receive such remuneration as follows—that is to say —(a) For attending to give evidence at any inquest whereat no post-mortem examination has been made by such practitioner one guinea (b) For making a post mortem examination of the body and for attending to give evidence thereon two guineas ’ The plaintiff in such a case as that described would presumably, therefore, have to establish either that the coroner was obliged to allow the fees of a medical witness who ‘attended’ the inquest, whether he refused to answer reasonable and relevant questions or not, or that in the particular case under discussion the answers given or refused and the conduct of the witness generally were not such as to disentitle him from receiving his fees In the second event supposing it were decided upon the first point that the coroner might on proper occasions withhold the fees, the question would be discussed whether and to what extent any other court could review the coroner's exercise of his discretion If the matter goes further it may prove of interest to coroners desirous of knowing the limitations placed upon their powers and to medical witnesses who are sometimes not well treated at inquests It is to be observed that in criminal courts the fees of medical witnesses are in the discretion of the court as to their amount The fee of not more than a guinea, or whatever the maximum sum may be in the circumstances, “may’ be paid to the witness At coroners' inquests the witness is “entitled to receive’ a definitely prescribed remuneration if he is to receive anything at all The latter is a more satisfactory arrangement for all parties, as the witness knows what he is going to get and, were it universal, magistrates and others would not be tempted to try to economise public funds at the expense of witnesses who have performed a public duty The want of uniformity is a matter worthy of attention and remedy

SUBPERIOSTEAL FRACTURES OF THE HUMERUS IN CHILDREN

AMONG the fractures formerly overlooked which have been revealed by skiagraphy are “subperiosteal fractures” in children This class of injury has been described by American surgeons but does not appear to have received much attention in this country The ordinary green stick fracture is, of course, subperiosteal but the “subperiosteal fracture differs from it in that there is no deformity but a clean cut crack or cross fracture without any bent or half broken layer of bone The intact periosteum prevents crepitus or mobility This form of fracture appears to be common in children and must therefore often be overlooked In the *Boston Medical and Surgical Journal* of August 11th Dr J S Stone has reported five cases of subperiosteal fracture of the humerus which were observed in the Children's Hospital, Boston between May 18th and Dec 30th 1903 In the first case, a girl, aged 11 years, fell from a swing, injuring the right arm When she went to the hospital two days later she could not raise the arm from the side but the forearm was freely moved No fracture was found As she was very nervous the disability was thought to be hysterical and a sling was applied Some atrophy of the deltoid followed After a fortnight the arm could be raised somewhat and after six weeks movements were perfectly free Three weeks later she was examined more thoroughly and an irregularity of the surgical neck of the humerus was found There was slight forward projection of the upper end of the lower fragment The amount of callus was small A radiograph confirmed the diagnosis which, however, was made only in view of the two next cases In the second case a girl, aged 10½ years was taken to the accident room She had that day fallen down four or five steps, hurting the left arm She could not raise the arm from the side Careful examination revealed no fracture Injury of the deltoid was diagnosed On the following day she went to the out patients' department There were then marked swelling and ecchymosis in front of the neck of the humerus and slight thickening of the bone The arm could be moved freely but it could not be abducted Passive movement was free in all directions and caused little pain A radiograph showed a transverse fracture of the surgical neck The upper end of the lower fragment projected forwards and there was impaction of about a quarter of an inch posteriorly, causing slight forward curving No attempt was made to correct the slight deformity and splints were applied Considerable atrophy of the muscles of the shoulder followed in a few days Perfect movement was regained In the third case a girl, aged six and a half years, was taken to the hospital Two and a half weeks before she fell from a fence Afterwards, in spite of the fact that she had no pain, she could not raise the arm from the side There were considerable atrophy of the deltoid and supraspinatus muscles, slight atrophy of the infraspinatus and complete inability to abduct the arm A slight bony projection was felt in the surgical neck where a radiograph showed a transverse fracture. There was slight displacement forwards of the upper end of the lower fragment with slight impaction posteriorly and forward curve. A shoulder cap and sling were applied. The resulting callus was small and complete movement was regained. The remaining two cases are quite similar. The cases resemble one another so much that diagnosis of subperiosteal fracture of the neck of the humerus should be possible without the aid of the radiograph. The fractures occurred after the age at which greenstick fracture is most common, were produced by a fall on the outstretched arm, and were followed by inability to use the deltoid and to raise the arm from the side. Atrophy of the deltoid and muscles of the shoulder took place. There was a sharp, bony ridge on the anterior surface of the neck of the humerus which might easily be overlooked. Therefore, when a child cannot abduct the arm after a fall and presents none of the ordinary signs of fracture or dislocation, careful examination should be made to detect tenderness and thickening anteriorly below the head of the humerus. These signs should establish the diagnosis of fracture of the surgical neck and should deter the surgeon from further attempts to obtain crepitus by force. Of course it will be well to have a skiagraph taken, especially if there is any doubt.

THE TRIALS OF SMALL MOTOR-CARS.

THE recent trials of small motor-cars near Hereford cannot fail to interest many of our readers. Full accounts with the official results and awards are given in the numbers of the *Autocar* of Sept. 10th and 17th. The report of the judges shows the great improvement in small cars made during the last year. In 1903 there were only two or three makes of car under £200 in price which could be regarded as soundly built and trustworthy; to-day there are dozens. The cars in the Hereford trials were arranged in four classes according to price, varying from £150 to £200. They had to make 12 runs of about 50 miles each with the view of testing their power of making such runs without stop or breakdown. 35 competitors started and 26 completed the 620 miles. The report of the judges, which is minute and carefully drawn up, shows that the causes of breakdown were rarely vices inherent in motor-cars but due in most instances to slovenly workmanship in the fitting and connexion of water or petrol pipes, parts of the cooling system or of petrol service. The working parts of the cars are pronounced as very good but in many cases badly put together, these working parts, such as gear-cases, tanks, and steering-gear, being inefficiently placed on the frames. The frames themselves have very much improved and the tyre troubles were exceptional, as might be expected with lightweight cars. The observed errors of construction are all such as manufacturers can easily avoid and will avoid when their market extends. The cars varied in nominal horse power from six to ten and few carried more than two passengers. One engine only had two cylinders but to sell a two-cylindered car at this price two years ago would have been quite impossible. The tables drawn up by the judges contain comparisons of the competing cars in such important points as "ease of manipulation, brake tests, petrol consumption, comfort of passengers, hill-climbing, vibration, noises," for all of which awards were made according to a previously arranged scale of marks. For general excellence of design and construction medals were given and future purchasers of small cars would do well to consider the list. The De Dion-Bouton firm, which has always had a deserved reputation for small cars, is now finding keen competitors in Birmingham and Coventry, for the Wolseley, Siddeley, Swift, and Humber companies have all taken good places in the results. The performances of these little cars will unquestionably produce wide changes in the methods of locomotion of medical men all over the country, for the standard of work performed was exacting and the results were excellent.

"BOGUS BUTTER."

HOWEVER slack or apathetic our honest traders may be, there seems to be no want of enterprise on the part of those whose aim is to swindle. On Sept. 14th at Heywood a young man with several aliases, all purporting to be Irish, was fined £40 and costs, with three months' imprisonment in default of payment, "for selling butter which was not of the nature, substance, and quality demanded." He had been previously convicted for a similar offence. Fraudulent dealing as to food deserves severe punishment. There were two cases and the fine was £20 and costs in each case. The first sample taken showed 11½ per cent. of water and 80 per cent. of fats other than butter and it was said to be "nothing less than margarine and not good margarine at that." We cannot suppose that those who sell margarine as butter would be very particular as to the source or wholesomeness of the fats which they use. The solicitor for the Lancashire county council alleged that the defendant was one of a gang of men who were engaged in a butter swindle in different parts of the country. They took shops in various towns and whenever a sample was taken at one of them there was a general "merry-go-round" of the men engaged in the business, so that it was extremely difficult to find who were the principals and really responsible. A handbill was issued at the Heywood shop and similar ones were posted in five other towns, so that some parts of Lancashire are well supplied no doubt with this "bogus butter." The poorer people who are the chief customers suffer heavily from high prices for inferior food. There was a sequel to this case on Sept. 19th, when at the Stalybridge police-court this same enterprising young man was again summoned for selling "bogus butter" on two occasions and fined £20 for each case. The analyst's certificate said in regard to each sample: "This is not a sample of butter; it contains 100 per cent. of margarine." It seems that when short of their "butter" at Heywood they sent to the shop at Stalybridge for it and *vice versâ*. If these fines of £80 occur frequently the profits of the fraud will be somewhat reduced and sufficiently so, let us hope, to make their perpetrator turn his attention to other fields of "industry."

THE STATUS THYMICUS.

THE few carefully examined cases of status thymicus that have been recorded in recent years have served to throw little light on this curious and grave constitutional condition the pathogenesis of which is still obscure. Persons affected with this diathesis are liable, under anæsthesia for example, to collapse and the danger of sudden death. An account of the symptoms and of the appearances, anatomical and pathological, of the status thymicus was given in an annotation in THE LANCET of March 24th, 1900, p. 869. The condition known as status thymicus is defined as a constitutional disorder characterised by persistence and hyperplasia of the thymus and lymphatic glands, frequently associated with arterial hypoplasia and the osseous evidences of rickets. In the *New York Medical Journal* of August 27th Dr. Frederick Simmons records a case of special interest in which a thorough post-mortem investigation was made. Such records are very rare and in this case status thymicus was suggested as the cause of death and the diagnosis was verified by the necropsy. The patient was a boy, aged ten years and seven weeks, who was under

Dr. Simmons's care suffering from muscular twitchings and "presenting a typically adenoid facies." Examination showed the presence of enlarged tonsils and naso-pharyngeal adenoids. The chest was flat and marked with costo-sternal nodules. The extremities of the long bones were somewhat enlarged but there were no other signs of rickets. The heart was normal to palpation and auscultation. A long and tight prepuce was discovered and at the operation decided on for removal of the naso-pharyngeal adenoids the patient was circumcised. He took chloroform well and the circumcision was rapidly performed. The head was then lowered and the adenoids were removed without further anæsthesia. At the last stroke of the curette the anæsthetist remarked a sudden failure of the pulse and immediate cyanosis of the face. Respiration suddenly came to a stop. Artificial respiration was at once applied by Silvester's method, stimulants were administered in the form of amyl nitrite and nitro-glycerine, strychnine, and electricity to the chest, while inhalations of oxygen were given. After working for three minutes respiration returned and continued for three or four inspirations and expirations, and then ceased. Artificial respiration was then resumed and continued for 45 minutes, while all the other means mentioned above to restore the heart and breathing were applied. The pulse, however, never returned, cardiac action remained imperceptible, and the attempt to revive the patient had to be abandoned finally as hopeless. The necropsy revealed an extreme venous engorgement with dark blood of all the organs, including the brain. A few adhesions between the dura mater and the cerebral hemispheres were present as well as a few scattered tubercles in the meninges. Upon opening the chest a large thymus gland deeply congested and measuring two by three inches was found. The lungs were normal. There was some frothy mucus in the bronchi. The heart was not enlarged. The right ventricle was perfectly flaccid, the left being firm and empty of blood had apparently stopped in systole. The myocardium and valves were normal. The bronchial and mesenteric lymph glands were enlarged everywhere (hyperplasia) and the spleen was very dark and congested, the case being clearly one of status thymicus.

LUNACY IN AUSTRALIA.

LUNACY administration in the colony of Victoria is at present to some extent in a state of transition owing to a new Lunacy Act which is now becoming effective. In the lunacy statistics for 1903, issued by the inspector of lunatic asylums, an outline of which was given by our Australian correspondent in THE LANCET of August 20th, p. 570, reference is made to the possibility of some modifications of the existing system being introduced. The powers contained in the new Lunacy Act of Victoria "will no doubt be used," says the report, "to provide at an early date some institutions, such as receiving houses, where the sanity of doubtful cases can be tested. It has been suggested that persons suffering from acute alcoholism should be received into these institutions. The wisdom of the policy of mixing such cases with the doubtfully insane is," adds the inspector of lunatic asylums, "open to serious question, and it must greatly increase the cost of buildings both in structure and upkeep." It is shown that the cost of maintenance of all institutions and patients during the year amounted to £135,795, the actual cost of maintenance of patients being £131,042, and the average weekly cost per patient 11*s.* 7*d.* Deducting the amounts received from the relatives of patients and from other sources the net cost of maintenance still remains as high as 10*s.* 4*d.* per patient. Economy has been practised wherever practicable and expenditure kept within the limits consistent with the well-being and comfort of patients. The introduction of receiving houses would add seriously to the burden of cost unless the cases admitted are restricted to actual and early cases of insanity only. The average recovery-rate for patients in all institutions during the year was calculated as being 7·4 per cent. of the average number resident, while the rate of mortality was 8·3 per cent. "The possibility of keeping our patients out in the open air all the year round," concludes the report, "makes tubercular disease far less dangerous than in England. As, however, there are severe cases in all our asylums I would again recommend," says the inspector of lunacy, "that special wards be erected at the Sunbury Asylum where they can be segregated." Special precautions have been taken at the Idiot Asylum, Kew, to prevent danger of overcrowding and contagion from tuberculosis.

"MACGREGOR FUND" IN AID OF THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE: CONGRATULATORY BANQUET TO SIR *WILLIAM MACGREGOR.*

Sir William MacGregor, M.D., K.C.M.G., C.B., late governor of Lagos, who has been recently appointed governor of Newfoundland, was entertained to dinner at the Palatine Club, Bold-street, Liverpool, on Sept. 16th by Sir Alfred Jones, K.C.M.G., the chairman of the Liverpool School of Tropical Medicine and president of the Liverpool Chamber of Commerce. In addition to the principal guest were the Lord Mayor (Sir Robert Hampson), Sir Ralph Moor, K.C.M.G., Professor Rubert Boyce, F.R.S., and others. Sir Alfred Jones, in proposing the toast of the health of Sir William MacGregor, described him as the best governor whom West Africa ever had. They were very sorry to lose him and he congratulated Newfoundland upon having acquired him. One thing he could never forget and that was the way in which Sir William MacGregor had helped the Liverpool School of Tropical Medicine to make the tropics healthier than they were; in fact, none could dispute that Sir William MacGregor was the father of that school. Sir William MacGregor, who was warmly received on rising to respond to the toast, said that in going to Newfoundland he was not going away from the influence of Liverpool. As long as he had known them the merchants of Liverpool had always recognised that the possession of money brought along with it a certain responsibility. There were among them a strong vein of unselfishness and a recognition of native rights, as exemplified by their assistance to the Lagos Institute and the splendid work of the Liverpool School of Tropical Medicine, of which Sir Alfred Jones was the founder. The latter work, he assured them, was having a great influence not only on the traders but also on the native races, and they would find that in proportion as they increased the sanitary condition of West Africa they would increase their own trade. He trusted that before long the school would be put on a national basis and would be able to extend its work into the enormously extensive sphere only the fringe of which had as yet been touched. The toast of "The Liverpool School of Tropical Medicine" was responded to by Professor Boyce who said that Sir William MacGregor was one of the first to take to heart the lessons enunciated by Major R. Ross in regard to the health of West Africa. Many young men without prospects were working in the direction of promoting health in West Africa and one of them, a Canadian, while engaged in that work was paying another man to make investigations in other directions. Sir Alfred Jones said that he was desirous of raising a fund, to be called the "MacGregor Fund," in aid of the School of Tropical Medicine, to which he would subscribe £500. He was followed by Mr. John Holt (vice-chairman of the African Trade Section of the Chamber of Commerce) who said he would contribute £200 and by Mr. H. Cotterell who promised £50. Mr. Miller said that his firm would also subscribe.

THE MUNICIPALISATION OF MEDICAL SERVICE.

WE shall watch with interest a new experiment in contract practice which is on its trial on a large scale in the city of Zürich. In this socialistic centre the medical profession are, as it were, "pooling" their practices. There is a communisation of their services and each inhabitant is to pay a yearly contribution of 3*s.* 7½*d.* The income from this source, which approximately amounts to £20,000, is divided in equal shares among the 40 medical men who constitute the "pool." A simple calculation shows that the income of each will be £500 per annum. Although there are many theoretical advantages in annual contracts between medical advisers and their patients, more especially when the former take upon themselves the duty of keeping their patients in health as well as of attending to them when they are actually ill, nevertheless there are practical disadvantages which for the present, at all events, would be calculated to interfere with the success of any such plan if extended to the better class practices of this country. We are not yet in possession of the working details of the scheme on trial in Zürich. We presume that some such method is in operation as that adopted by provident dispensaries and clubs in this country—that is to say, that a certain definite group of patients is allocated to each medical man, and that only within limits are the former permitted to choose their own medical adviser. If the citizens of Zürich are permitted to exercise their own discretion as to the medical man whom they are to consult it is obvious that the most popular practitioners will be seriously overworked. On the other hand, if the patients are compelled to intrust the care of their health to the hands of a man in whom they have no confidence there will be ample room for discontent.

PERITONITIS DUE TO THE PNEUMOCOCCUS.

RECENT bacteriological researches have proved that the pneumococcus may produce pathological changes in many parts of the body other than the lungs; thus cases of peritonitis, of suppurative or phlegmonous gastritis, and of appendicitis occur from time to time in which the pneumococcus can be demonstrated as the cause. Dr. M. von Brunn discusses the general features of pneumococcus peritonitis in *Beiträge zur Klinischen Chirurgie*, Band xxxix., Heft 1, and summarises his results as follows. The condition is relatively a rare one; it occurs more often in children than in adults and more in girls than in boys. It may be primary in the peritoneum or may be secondary to affections of the lung or middle ear due to the pneumococcus. Considered from the clinical standpoint the chief features of the affection are in typical cases an onset like that of an acute peritonitis, passing afterwards into a chronic stage with relatively few peritoneal symptoms. Pathologically, the appearances produced are suggestive, though, of course, the diagnosis can only be made after bacteriological examination. The process leads at an early stage to adhesions and to localisation of the exudate, which is very coagulable and rich in fibrin, of greenish-yellow colour, and not offensive. The prognosis is favourable; spontaneous recovery though possible is rare. The treatment consists in freely opening the abscess cavity and draining, recovery being the rule. There are perhaps few organisms producing such widely different affections as the pneumococcus and it would be a matter of great interest and value if the mode of entry to some of the organs primarily affected could be more definitely determined, for in the primary peritoneal cases Dr. von Brunn admits that the explanation of their origin is far from satisfactory. It has been suggested that infection occurs in some cases through the appendix but this would certainly not account for all. The pneumococcus seems to have a predilection for serous membranes as well as for the lung, since pleurisy, pericarditis, peritonitis, and meningitis due to it are all described, and in all the cases the exudate presents similar characters to those described by Dr. von Brunn in peritonitis.

RUSSIAN PRECAUTIONS AGAINST CHOLERA.

THE chief medical inspector has returned from a six weeks' tour in the country bordering on the Persian confines where he concerted measures for preventing the importation of cholera from Persia. He asserts that the most comprehensive arrangements have been made particularly to keep the workmen's quarters of the towns clean and the workpeople well supplied with good water, food, and healthy houses. Orders have been issued for instant isolation in case of suspected illness and the disinfection of all things connected with the sick. At the ports on the Caspian Sea observation stations have been established, with special steamers attached to the health service, and a complete series of hygienic stations have been provided for the whole length of the river Volga, the great water highway leading from the Caspian Sea through a great part of Russia. Particularly Astrakhan and Baku have to undergo a thorough cleaning. In the latter town incredible filth had been found in the workmen's quarters. There unhealthy houses are to be closed until they are put into a sanitary condition and temporary barracks meanwhile are to be provided. The medical staff and sanitary officers have been largely increased, hospital accommodation has been selected, and abundant supplies of disinfectants and medicines are being laid in. "Unfortunately," says the notice in the *Novoe Vremya*, "our towns are in such an insanitary state that it will require tens of millions of roubles and years of time to answer to the medical requirements." The Transcaucasian territory is the real danger zone. Temporary hospitals have been installed there and the medical staff has been reinforced, including drafts from the Red Cross Society. Chief Inspector Anrep does not anticipate an invasion of cholera this year but profiting by experience gained from past epidemics he entertains grave fears for next spring and summer. Further details as to cholera in the Near East will be found in the communication from the British delegate to the Ottoman Board of Health which appears in another column.

THE death on Sept. 16th is announced of Mr. Charles W. Izod, M.R.C.S. Eng., L.S.A., of Esher, Surrey, which took place at Whitehall Court, Westminster. We gave a concise account of this gentleman's notable record in THE LANCET of May 17th, 1902, p. 1434. Mr. Izod had been surgeon at Claremont, near Esher, to the household of Leopold I., King of the Belgians, to that of the late Queen Victoria, to that of the King of the French, *Louis Philippe* and his family, and to that of the Duchess of Albany. He retired in June, 1902, after 55 years' practice.

THE winter session of the West London Post-graduate College, West London Hospital, Hammersmith-road, W., will commence on Thursday, Oct. 13th. The opening address will be delivered by the Right Rev. the Lord Bishop of Oxford at 5 P.M. on that date and medical men desirous of attending can obtain a ticket on applying to Mr. L. A. Bidwell.

DR. J. Lorrain Smith, the newly appointed professor of pathology, will open the medical session of the University of Manchester by delivering an introductory address on Monday, Oct 3rd, at 4 30 P M, to which members of the profession residing in or near Manchester are invited

THE address at the opening of the Medical Faculty of the University of Birmingham will be delivered by Dr P H Pye Smith on Oct 3rd

THE EVOLUTION OF MAN'S DIET

BY HARRY CAMPBELL M D, F R C P LOND,
PHYSICIAN TO THE NORTH WEST LONDON HOSPITAL AND TO THE HOSPITAL FOR NERVOUS DISEASES WELBECK STREET

III [1]

THE RELATIVE QUANTITIES OF ANIMAL AND VEGETABLE FOOD CONSUMED DURING THE SUCCESSIVE DIET EPOCHS

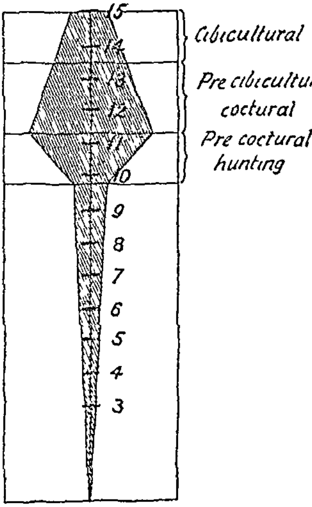
WE may now fittingly consider the fluctuations in the relative quantities of animal and vegetable food which have occurred in the diet of evolving man at various stages As our anthropoid and homo simian precursors grew in intelligence they were naturally able to secure more and more of the much coveted animal food such as insects, grubs reptiles, eggs, birds, and the smaller game and there took place in consequence a steady rise in carnivorism during the anthropoid and homo simian stages but especially during the latter Nevertheless, we may regard it as certain that until the hunting and fishing period was reached our ancestors remained essentially vegetarian With the advent of this period however, they greatly increased in carnivor [illegible] *actually more carnivorous than* [illegible] carnivorous than vegetarian because [illegible] period, when by means of cookery man had greatly increased his supplies of easily digestible vegetable food he still continued to depend very largely upon animal food as is proved by the dietetic customs of existing pre cibiculturists It is true that many of these peoples inhabit barren regions affording a comparatively meagre supply of vegetable food but it may safely be asserted that *not the most luxuriant* and bountiful region in the world is capable of supporting by means of its uncultivated flora alone any existing pre cibicultural people even with the great help to be got from their elaborate systems of preparing vegetable food How much less capable therefore, must even the most fertile regions have been in pre coctural ages Now, though it is certain that animal food was included in the dietary of our anthropoid precursors there can be no doubt that they were not so incapable as man is of subsisting wholly on natural vegetable products, and from this we may infer that the evolving man during the homo simian and early hunting periods lost much of his power to digest raw uncultivated vegetable substances

Just as the discovery of cookery led to an increase in the quantity of vegetable food consumed so also did the introduction of agriculture and in an even greater degree for while the breeding of animals augmented the available quantity of animal food it did not augment it to anything like the same extent that agriculture augmented that of the vegetable food Certain communities or sections of communities do indeed at the present time subsist mainly on animal food, but taking agricultural communities at large they are certainly in the main vegetarian, and some, like the Hindus almost entirely so

To sum up our ancestors though remaining chiefly vegetarian slowly increased in carnivorism during the anthropoid and [illegible] chiefly carnivorous during the [illegible] carnivorous and half vegetarian [illegible] coctural period and thenceforward increasingly vegetarian again until the period of stationary agriculture was reached

As to the truth of these generalisations there can I think, be no doubt That man and his precursors have for hundreds of thousands of years been largely carnivorous that the incipient man actually subsisted more upon animal than vegetable food, that in fact, after evolving from his homo simian precursors man has mounted up all but the last one or two rungs of his evolutionary ladder on a highly animalised diet is as certain as anything well can be This cardinal fact must ever be borne in mind by those who seek to devise a rational system of diet for modern man To assume that disease and premature death necessarily result from taking animal food and that in matters dietetic physiological salvation is to be found in vegetarianism alone is to ignore the fact that for an extremely long period (10th to 11 5th grade) of man's phylogeny *he was actually more carnivorous than vegetarian* I am not forgetting that man was most carnivorous when in the hunting stage—when, namely, he was leading a highly active out door life, that during the agricultural period his organism became, and is still becoming more and more adapted to a cooked vegetable diet, that a large quantity of animal food often proves injurious to the modern man when leading a sedentary life, and that even the carnivorous dog when compelled to spend most of its life lolling about a house or chained up in a back yard is unable to tolerate a purely animal diet All this is very true, but because a mainly animal diet is apt to be injurious to those leading sedentary lives we must not on that account and in the face of his past history assume that the only diet suitable for man is the purely vegetable

FIG 5



ALTERATION IN THE NATURE OF THE VEGETABLE FOOD CONSUMED DURING THE SUCCESSIVE DIET EPOCHS

Before the introduction of cookery all vegetable substances save the luscious fruits needed considerable mastication in order to break up their cellulose framework, and the denser and more abundant this framework the more mastication did they stand in need of Naturally, therefore owing to that innate desire to economise labour which characterises all sentient beings the denser and more bulky vegetable substances would be less in demand than the less dense and more concentrated and similarly, insipid, bitter or acrid foods would find less favour than more palatable kinds *Consequently* as the evolving man became during the homo-simian and hunting periods but especially the latter less and less dependent upon vegetable food there was a progressive abandonment of the most dense, bulky, and unpalatable kinds in favour of their opposites and thus it was that by the beginning *of the coctural period man had* by discarding lost the power of digesting in the raw state many of the coarser and more unpalatable varieties on which his anthropoid ancestors subsisted and on which presumably, existing anthropoids still to a large extent subsist

With the advent of cookery and the extra quantity of easily digestible vegetable food which it rendered available man became still less dependent upon that which was raw and uncultivated and this led to a further abandonment of, and loss of power to digest, the least choice varieties. Finally, agriculture has rendered man wholly independent of raw, uncultivated vegetable food by placing at his disposal an abundance of pleasant, easily digestible and highly nutritious vegetable foods, which are consumed either in the raw state, as in the case of fruits, or, as more generally happens, after elaborate preparation. Hence, he has lost the power of digesting in the unprepared state all but the very choicest varieties of wild vegetable foods, such as the luscious fruits and certain nuts, and even the latter he often finds difficulty in digesting, though this, it must be acknowledged, is usually due to defective mastication.

---

[1] Nos. I and II were published in THE LANCET of Sept. 10th (p. 721) and 17th (p. 848), 1904 respectively

ALTERATION IN REGARD TO THE SACCHARIDES INGESTED DURING THE SUCCESSIVE DIET EPOCHS.

Before the agricultural period the supply of soluble saccharides—grape sugar, fruit sugar, cane sugar—was comparatively small and was derived mainly from the luscious fruits and from honey, which from the anthropoid right into the agricultural epoch has constituted an important source of saccharide for the evolving man. With the advent of the agricultural period, however, and the cultivation of the date, the fig, the banana, and in later times the sugar cane and beetroot (from both of which cane sugar is extracted in enormous quantities), the supply of soluble saccharide has reached astounding proportions.

The quantity of starch consumed increased with the introduction of cookery, by means of which many vegetable substances useless in the raw state were converted into valuable foods; and it was, of course, still further increased by the introduction of agriculture. And not only was more starch now taken, but this increased quantity was subjected to far less mastication and insalivation than in pre-coctural times and consequently the quantity entering the stomach in a crude state underwent a great increase, and in this age of pap, when it is the custom to consume starch for the most part in the soft, pappy, or even liquid form, it has gone up by leaps and bounds, a circumstance which I hold to be responsible for a great deal of disease.

INFLUENCE ON FUNCTION OF THE CHANGES IN THE DIET OF THE EVOLVING MAN.

The ability to digest animal food rose and fell with the quantity consumed during the various diet epochs and was thus greatest during the early hunting stage, while the ability to digest raw vegetable foods, especially of the coarser kinds, has steadily diminished from the anthropoid stage until the present time. One can scarcely doubt that our anthropoid ancestors had special powers of coping with cellulose and, one may add, with the bitter and acrid constituents of many vegetable foods; it would be interesting to make observations on existing anthropoids in regard to this point. It is known that some of the vegetable foods of the great apes are bitter, and that sour foods are not distasteful to some at least of them is shown by the fact that they sometimes display a great liking for them. Seeing that not even the herbivora secrete juices capable of digesting cellulose, but depend upon bacterial action for its digestion, one would not expect the anthropoids to secrete a ferment capable of dissolving it but there can be little doubt that they possess special facilities for dealing with this substance.

Up to the discovery of cookery mouth-digestion was more active than it has since been, owing to the prolonged trituration to which it was necessary to subject the raw vegetable foods. One may presume, therefore, that the amylolytic power of the salivary glands was greater in pre-coctural times than it has since become, especially in these days of pap, when the starchy foods slip down into the stomach with a facility which can only be characterised as disastrous.

Inasmuch as up to the coctural period most of the saccharides were swallowed in the soluble form—e.g., grape sugar, fruit sugar, cane sugar, maltose, and the dextrines—we may assume that up to this time the stomach and intestines were intolerant of large quantities of starch, but that after the introduction of cookery their ability to cope with this substance steadily increased, becoming ultimately greatest in those communities which, like the Hindus, are essentially vegetarian. In like manner the power of digesting cane sugar must have been increasing within quite recent times in correspondence with the large quantities now consumed.

The functional adaptations just referred to have been not only individual but racial, the latter having been achieved by natural selection—i.e., by the survival of those best able to adapt themselves to the dietetic changes. We see this racial adaptation going on under our very eyes. Tens of thousands of starch-deluged and bottle-fed children are in our own country yearly weeded out, those best adapted to these modes of feeding surviving and transmitting their digestive peculiarities to their offspring. Thus a race is evolving which is capable of being reared on cow's milk during infancy and of digesting enormous quantities of starch and sugar.

INFLUENCE ON STRUCTURE OF THE CHANGES IN THE DIET OF THE EVOLVING MAN.

These various phylogenic changes in digestive function have had, it is needless to say, a structural basis, though the gross structural changes which have taken place in man's digestive system during his gradual ascent are less pronounced than one might perhaps expect. We have, of course, no exact anatomical knowledge of the digestive organs of our anthropoid precursors, but we know that they must have been very like those of existing anthropoids; and by striking their anatomical mean in these animals we shall get a fairly accurate notion of them as they existed in the homo-simian. At present it is not possible to determine this mean, for, unfortunately, the necessary facts are not forthcoming. One thing, however, is certain—viz., that there is a remarkable general resemblance between the digestive organs of man and of the anthropoids—a fact which renders it practically certain that they have undergone little gross structural change since anthropoid times. It is to be hoped that the comparative anatomy of the digestive system in the great apes will soon be worked out in minute detail, so that we may be in a position to say what changes have taken place in it, as this would give a clue as to the dietetic changes which must have, *pari passu*, occurred. A few known anatomical peculiarities in the digestive organs of the anthropoids may here be referred to. The dental formula of the anthropoids is the same as for man, though the teeth of the former are larger and stronger than those of the latter, being evidently adapted for coarser and more vigorous work. The tongue of the anthropoids is said to be small, which is somewhat surprising. The lingual papillæ in the aged gorilla acquire a horny hardness and the circumvallate papillæ of this ape are arranged -shaped, as in man; in the chimpanzee they form a T or a +. Owen and Virchow state that the small intestines are devoid of valvulæ conniventes in all the apes, but it would appear that they do actually exist, though in a rudimentary form, in some; in any case, however, they are certainly not so developed as in man, and this constitutes one of the most striking anatomical differences in the digestive systems of man and the great apes. In all the great apes the cæcum is provided with a vermiform appendix; in the orang this structure is long and convoluted; in the chimpanzee it is constricted at its origin. In none of the great apes is the cæcum provided, as in the case of the monkey, with a mesentery. The liver of the orang bears a remarkable resemblance to that of man (Virchow). The gall-bladder of the chimpanzee is considerably larger than in man. Professor Keith in a letter to me lays stress upon the great similarity between the digestive organs of the anthropoids and of man, the main differences according to him being the greater muscularity of the stomach and the less complete development of the valvulæ conniventes in the former case. Not only do we lack a minute knowledge of the anatomy of the digestive system in the great apes, but we are not even able to state precisely how far existing pre-cibicultural peoples differ in regard to their digestive organs from us moderns. Information on this point is much needed. It does not seem likely that any marked change has taken place in the digestive system since the negro, Mongol, and Caucasian diverged from their common ancestor, inasmuch as, though there may be differences in detail, it is practically the same in all of them; and this suggests that the chief differences between man and his anthropoid precursor in respect of the digestive system were brought about before the specialisation of the three great families—i.e., in the simian period, prior to the evolution of the tenth grade; and if such is the case we may conclude that the food of the evolving man underwent very decided changes during that period.

Probably the most obtrusive change which has taken place in the alimentary system since the anthropoid period is to be found in the maxillary apparatus, but this is not wholly, if indeed mainly, connected with diet. It should be noted that primeval man, even as late as the latter part of the pre-coctural period, was obliged to use his jaws in eating [illegible] as did his anthropoid [illegible] *oh*, perhaps, on account [illegible] uantity and density of [illegible] is period But against [illegible] quantity of animal food consumed, which must have led to a corresponding increase in what may be called the carnivorous use of the jaws, in which the masticatory muscles are made to contract with greater force, though for a shorter time, than is required by raw vegetable food.

Now, there can be no doubt that long before the discovery of cookery the jaws had largely lost their bestial character and had assumed an essentially human aspect, and it is obvious from what has just been said that the profound change which they underwent in the pre coctural period cannot be explained by reference to dietetic changes It was probably in part brought about in correlation with the progressive expansion of the cranial cavity which has marked man's ascent from the anthropoid, but it was also largely due to the fact that as the evolving man came, in his encounters with other animals, to rely more upon his intelligence and less upon mere brute force he stood correspondingly less in need of massive prognathic jaws which constitute for a large number of animals the most deadly weapon of encounter. Directly man began to fashion weapons we may assume that he practically ceased to use his jaws as a means of offence and defence, and that thereafter the progress from prognathism to orthognathism was more rapid than during any previous period The changes in the maxillary apparatus which have taken place in civilised times have been connected partly with the increasing softness of the vegetable food, and have, perhaps, partly also been brought about by sexual selection, highly animal jaws being, in the woman at least, a bar to marriage.

INFLUENCE ON MENTAL AND SOCIAL EVOLUTION OF THE CHANGES IN MAN'S DIET.

We see from what has been already said what an important part food has played in influencing man's habits and social evolution—how the invention of weapons and other artifices for securing game changed the evolving man from a comparatively stationary being to a wandering hunter, how, again, [illegible] than heretof [illegible] finally, with [illegible] and less a n [illegible] was reached, it died right out (except as a pastime), a sufficiency of food being artificially produced by a small section of the community, leaving the remaining portion free to specialise in other directions, and so rendering the evolution of a complex social organisation for the first time possible.

We may here consider in some further detail the influence on man's mental and social evolution of the changes which his diet has undergone during each of the successive diet epochs. Directly the hunting stage was reached and primeval man exchanged his comparatively stationary life for a wandering one a great change came over his habits of life, a change which *cannot have failed to exercise a profound* influence on his evolution Among all existing primitive peoples the hunting is undertaken by the men and we may be sure that this was the case from the very beginning of the hunting period Hence it seems probable that with this period there began the first real division of labour other than [illegible] this exception [illegible] d the two sexes [illegible] much the same share in the food quest—in searching for fruits, seeds, roots, insects, grubs, eggs, and the like—though, as we shall see later, even at that early period the task of collecting the vegetable food may have been chiefly undertaken by the female section of the community, but when the men began *to devote themselves to the hunt the duty of gathering the* vegetable food fell more and more to the lot of the women, each sex possibly playing an equal part in securing food from among the smaller species of animals.

Man remained a hunter right through the early coctural period and well on into the agricultural, from, let us say, the tenth to the fourteenth stage, while, in fact, he was putting on 400 cubic centimetres of brain tissue, and one can hardly doubt that this circumstance profoundly influenced his mental evolution and played no small part in causing the mental differences between the two sexes—e g , the greater development in the man of nervous activity, love of adventure, courage, bellicosity, ingenuity, and intellectuality generally With the advent of the hunting period mental evolution received, in fact, a great impetus, but all in *favour of the development of the male* His observant faculties, inventive powers, and cunning were called into play as they had never been before He was led carefully to observe the habits of animals, to devise means of deceiving them, to invent traps for ensnaring and weapons for destroying them, while his courage, his willingness to encounter danger and his acumen in avoiding it, were continually being tested; and we may be quite sure that those hunters who showed the greatest aptitude in these regards stood the greatest chance of survival, were most likely to secure the largest bags, to be recognised as leaders, and to leave the most numerous offspring to inherit their excellences, and seeing that natural variations appearing in one sex are on the whole more apt to be transmitted to the same than to the opposite sex—seeing, too, that the human male remained for some hundreds of thousands of years essentially a hunter—there has been ample opportunity for these several qualities to become accentuated in the male sex

We may further trace a relationship between the diet epochs and man's fighting propensity In the pre coctural hunting period the family constituted the social unit It was only possible to hunt in small numbers, large numbers scaring the game away There was thus little opportunity for combinations among families and inasmuch as most of the man's time was occupied in the food-quest none but very desultory and spasmodic fighting was possible It is unlikely that food was to any extent stored at this time and it is obvious that systematic warfare cannot be waged on an empty stomach. But when the discovery of cooking and the practice of storing vegetable food released the hunter somewhat from his occupations tribal organisation and warfare became more common, especially in seasons of plenty, though it was not until the early cibicultural *period was reached that organised* warfare received its chief development The increase in the supply of food which marked this epoch rendered tribal organisation possible and man's fighting instinct, now at its acme, was allowed full play This instinct, for such it is, was not at first anti social except in so far as it was connected with the sexual impulse which impels all polygamous males to fight for the possession of the females It presumably took its origin in the need which man, in common with all animals, had for self protection, and while doubtless strengthened by the development of sexual combativeness it probably became still further accentuated during the hunting period, when man took on the aggressiveness of the carnivorous animal All the carnivora are fierce fighters, [illegible] and his [illegible] terrific [illegible] at there [illegible] greatly intensified during the hunting stage He made ruthless war upon every species of lower animal that crossed his path. His instinct to kill now developed in its most acute *form* When, therefore, with the increase of vegetable diet which came with the early coctural period and still more with the period of food culture he had leisure to turn aside from his onslaught on the lower animals it is scarcely surprising that his combative impulse should find vent in warring upon his own kind Moreover, the beginnings of possessions of value now frequently provided a *casus belli*. The early agricultural stage is probably the most horrible period of human bloodthirstiness, when man, unsoftened by the moral sense which slowly evolved with the slowly evolving social organisation, reached the very acme of his blood lust and insatiable desire for inflicting torture Now it was that fighting was [illegible] a means for some tangible and [illegible], slaves, or hunting-grounds, but [illegible] n order to secure scalps, heads, or other terrible trophies of war. I do not believe that this form of savage and devilish warfare was practised to any great extent before the cibicultural period. At the present day it is certainly not met with so much among the precibiculturists as among the early agriculturists, such as the natives of Africa, Borneo, and New Guinea.

(To be continued.)

THE FACULTY OF MEDICINE OF THE UNIVERSITY OF LONDON.

THE commencement of the winter session will witness the renewal of activity in all departments of medical education. Towards the end of October the Faculty of Medicine of the University of London will be called together by the authority of the vice-chancellor in order to elect a dean for the succeeding two years. It will come as a surprise to many and will be regretted by all that this meeting will mark the termination of the period of office of Mr. H. T. Butlin as first dean of the Faculty of Medicine of the University of London. By the statutes a dean of a faculty is elected for two years and is re-eligible for a second period of office only. Mr. Butlin having now rendered excellent service to the University for a period of four years the faculty is unable to ask him any longer to continue in office. The enthusiasm which Mr. Butlin has shown in furthering the development of the University on its new lines makes it certain that whether in office or not he will continue to render it service. It is much to be hoped, however, that Mr. Butlin may in the near future have further opportunities of actively and officially promoting the welfare of the University as a member of the Senate. Considerable responsibility rests upon the faculty in choosing its second dean. As time goes on there can be little doubt that the office of dean of the Faculty of Medicine of the University of London will become the most prominent position in the country in connexion with medical education. The presidencies of the various Royal Colleges will continue to be the highest posts of honour to which a medical man can be raised by the votes of his professional colleagues, the blue ribbons conferred upon the most eminent practitioners of medicine and surgery by those whose appreciation is a man's best reward. But if we rightly read the signs of the times the professional colleges will gradually yield to the universities the premier place as educational institutions. Admirable as has been the educational work of these colleges in the past and regretfully as we must see any curtailment of their activities, we cannot shut our eyes to the fact that their future destiny is to watch over the interests and to maintain the highest traditions of our profession rather than to secure the adequate education of those about to enter it. This separation of the professional and educational interests of the medical community, securing as it will the undivided energy of powerful organisations for the promotion of each interest, is likely to have a very beneficial result. It is well that the development of medical education should proceed on the broadest lines of educational progress and that those responsible for its direction should be in close touch with professors of every branch of knowledge. The scheme for a one faculty university has disappeared for ever and in the interest of medicine it is much to be hoped that before long the unequal preponderance of the medical faculty in London may be balanced by the proportionate development of each of the faculties which constitute the university. From its well-organised sister faculties the Faculty of Medicine will have much to learn and its capacity to learn and to take advantage of its acquired experience will in great measure depend upon the judgment with which it chooses its official head. Mr. Butlin has set all future deans an example which it will be difficult to surpass and the faculty should endeavour to secure as his successor one who will carry on the work in the able manner in which it has been inaugurated. Amongst the 350 members comprising the faculty the large number of suitable candidates is the only feature which should make the choice a difficult one. For the new dean and the faculty over which he will preside there is no lack of work if education in the great schools of medicine in London is to derive full profit from the reconstitution of the University. For the time being the scheme of concentration of early and preliminary medical studies has passed out of the hands of the faculty. The Senate has adopted the unanimous proposals of the faculty and an appeal committee is engaged in securing funds to start a university centre of preliminary medical education at South Kensington in accordance with these proposals. Meanwhile individual members of the faculty can give valuable assistance by bringing the appeal to the notice of influential friends and public bodies able to give financial help. So soon as the necessary funds are available the faculty will, no doubt, be invited to fill in the details of the scheme, the main outlines of which it has already submitted to the Senate for the organisation of the Institute of Medical Sciences.

While the scheme for the concentration of early medical studies outside the hospitals is satisfactorily initiated there is much to be done towards coördinating clinical study within their walls. The faculty is the common meeting ground of the clinical teachers from all the schools of medicine, and not the least important function that it is destined to achieve is to break down the barriers between the schools which have grown up as the result of many years of isolated work and mutual competition. In friendly discussion of proposals to strengthen their common university the partisans of different medical schools will learn that progress can be achieved more certainly by coöperation and the mutual sharing of burdens than by the competitive struggle for existence which has hitherto been the chief characteristic of the relationship of these vigorous institutions.

The faculty may well consider whether the unrivalled field for clinical study offered by the hosts of patients in public institutions in London is fully made use of for the training and information of students, for the continued instruction of qualified medical men, or for the advancement of the general sum of medical knowledge. We venture to assert that in every one of these directions the opportunities are very far from being fully utilised. The Faculty of Medicine provides the centre whence concerted action can be brought to secure the much-needed reforms in dealing with the great mass of clinical material which is at present wasted. A suggestion has been made that as a first step towards coöperation and as a visible bond of union between the schools of the University some of the best original work issuing from the wards and laboratories should be collected and published periodically as the Transactions of the Faculty of Medicine of the University of London. To such an enterprise we should offer a most hearty welcome. Although there are some estimable associations in London for enabling general practitioners to refresh their memories and to keep themselves abreast of modern developments of clinical methods, we feel that we shall not be accused of failing to appreciate their efforts if we assert that the higher class of post-graduate study is still awaiting the action of the University to establish it on a satisfactory basis. Amongst the teachers of the faculty it is to be hoped that a considerable majority is impressed by the degradation of true mental training that is resulting in England from the dominance of the examination system in medicine as in all other branches of study. The reconstitution of the University is largely the result of a revolt against examinational tyranny and it ought not to be impossible for the teachers to evolve a scheme whereby the work a student does in the laboratories and wards of a hospital shall have its due weight in determining his success at examinations. The junior teachers of the schools, who see so much of the evils of cramming for examinations, should remember that through the Faculty of Medicine their voices can be heard in the counsels of the University. Any scheme which they can persuade the faculty to approve will receive the sympathetic consideration of the Senate. The faculty as a deliberative and consultative body is essentially the meeting before which advanced views on all questions of medical education should be brought. Progress is only possible by the formation of a strong public opinion as to existing defects and possible remedies. It is much to be hoped that during the ensuing session the faculty may take its part in persuading the medical teachers in London that much remains to be done to insure that its University shall maintain its position as the greatest centre of medical education.

MORTUARY FOR STONEHOUSE (DEVON).—At the meeting of the Stonehouse urban district council, held on Sept. 13th, it was decided to erect a new mortuary, the old one being described by one of the members as a disgrace to the town.

CHOLERA IN MESOPOTAMIA, PERSIA, AND ARABIA.

(FROM THE BRITISH DELEGATE TO THE OTTOMAN BOARD OF HEALTH.)

ABSENCE from Constantinople has prevented me from continuing the story of the cholera outbreak in Asiatic Turkey and Persia. My last letter, which appeared in THE LANCET of July 16th, p. 176, brought the record down to the end of the first week in July. The most serious extension of the disease since then has been on the Persian side of the frontier, in Tehran and its neighbourhood. It has, moreover, spread to Meshed, Resht, and Astrabad and a single suspicious case—fortunately not followed by others—occurred early in August at Baku, on the Russian shores of the Caspian. The rumours that the disease had appeared in St. Petersburg and elsewhere in Russia are officially declared to be unfounded.

In Turkish territory the following has been the course of the outbreak in the last few weeks. At Basra the epidemic has, it is hoped, come to an end; the figures here in the last seven weeks of the outbreak were as follows:—

On July 6th	2 cases ...	2 deaths.
From July 7th to July 15th ...	2 ,, ...	2 ,,
,, ,, 16th ,, ,, 23rd ...	10 ,, ...	5 ,,
,, ,, 24th ,, ,, 30th ...	8 ,, ...	4 ,,
,, August 3rd ,, August 4th ...	2 ,, ...	2 ,,
,, ,, 5th ,, ,, 12th ...	5 ,, ...	1 death.
,, ,, 13th ,, ,, 19th ...	3 ,, ...	3 deaths.

Since the last date named no other known case of cholera has occurred in Basra.

At Bagdad, on the other hand, an outbreak of very considerable severity has been, and still is, prevailing. It will be recalled that the disease reappeared there on June 4th after an apparent absence of two months. The figures for the four weeks ending July 4th were given in my last letter. The following are the returns since that date:—

From July 4th to July 8th ...	3 cases ...	2 deaths.
,, ,, 9th ,, ,, 16th ...	4 ,, ...	2 ,,
,, ,, 17th ,, ,, 23rd ...	38 ,, ...	45 ,,
,, ,, 24th ,, ,, 30th ...	29 ,, ...	33 ,,
,, ,, 31st ,, August 6th ...	36 ,, ...	22 ,,
,, August 7th ,, ,, 13th ...	65 ,, ...	54 ,,
,, ,, 14th ,, ,, 20th ...	127 ,, ...	105 ,,
,, ,, 21st ,, ,, 27th ...	180 ,, ...	133 ,,

The totals for the present week will probably be still higher.

The outbreaks in the Shiah cities of Nedjef and Kerbela appear to have come to an end about the middle of July; from the former no cases have been reported since the 13th and from the latter none since the 20th of that month. At Suleimanieh, close to the Turco-Persian frontier, the mortality has been very high, as shown by the following figures:—

From July 12th to July 16th ...	47 cases ...	17 deaths.
,, ,, 17th ,, ,, 22nd ...	283 ,, ...	208 ,,
,, ,, 23rd ,, ,, 30th ...	342 ,, ...	469 ,,
,, ,, 31st ,, August 4th ...	131 ,, ...	228 ,,
,, August 5th ,, ,, 12th ...	83 ,, ...	162 ,,
,, ,, 13th ,, ,, 20th ...	39 ,, ...	51 ,,
,, ,, 21st ,, ,, 25th ...	32 ,, ...	31 ,,

It will be impossible to mention here the many places from which the presence of cholera has been reported. They are situated mostly along the valleys of the Tigris and Euphrates and in the adjoining plains. The disease has spread up the Tigris at least as far as Mossul, where an outbreak of some severity has recently begun. The highest [illegible] from Salahieh (in the Kerkuk [illegible] d a large number of villages in [illegible] rom among the numerous tribes inhabiting the lower reaches of both rivers. The extension of the infection up the Tigris to Mossul threatens Armenia, and through Armenia the Caucasus, with an epidemic; but the latter is still more seriously threatened by the alarming spread of the disease in Persia.

At the date of my last letter cholera had been epidemic for several weeks at Kermanshah and at many other places near the frontier; it has also spread to Kum and was reported to have appeared in Tehran itself, though nothing positive was then known as to the intensity of the outbreak there. Exact information is still lacking as to the extent of the epidemic in the capital or elsewhere but all reports [illegible] in the former at a very high [illegible] infection exists over a very [illegible] most exact figures have been [illegible] are as follows (in continuation of the figures given on p. 177 of THE LANCET of July 16th):—

From July 6th to July 12th ...	31 deaths.
,, ,, 13th ,, ,, 19th ...	21 ,,
,, ,, 19th ,, ,, 26th ...	(information lacking).
,, ,, 27th ,, August 2nd ...	6 deaths.
,, August 3rd ,, ,, 9th ...	14 ,,
,, ,, 10th ,, ,, 16th ...	10 ,,
,, ,, 17th ,, ,, 23rd ...	3 ,,

These figures have been furnished by the Turkish Consul-General at Kermanshah and are based on the returns of the local authorities; but according to reports from the Ottoman Embassy at Tehran they are much below the truth, as the latter state that the deaths at Kermanshah were at one time as high as 150 per day. From Kermanshah the cholera spread to a large number of other Persian towns and villages, some of which were mentioned in my last letter but one.[1] It reached Hamadan at the end of May or the beginning of June; in the first week of June five or six cases and two or three deaths were occurring there daily. The further course of the disease here is not fully known, but on July 6th it was reported from Tehran that 300 deaths daily had occurred at Hamadan in the preceding week. The infection seems to have spread thence to Kum, where from eight to ten deaths were occurring daily in the first half of June. The date of the first cases in Tehran is not known but some suspicious cases were reported in the second week in June and the epidemic seems to have increased rapidly. Almost the earliest case there was that of Dr. Vaume, the Turkish delegate on the sanitary board which is supposed to sit at Tehran. He had been sent by the Constantinople Board of Health on mission to Kermanshah and the surrounding infected districts and returned to Tehran disheartened by his inability to induce the Persian authorities to take any serious measures. Almost immediately after his return to the capital he was attacked by the disease and died after a short illness.

According to a report from the Ottoman Embassy at Tehran, dated August 2nd, the mortality in that city rapidly grew to 50 or 60 per day. It progressively increased to 100, 150, 200, 300, and even 500 a day. Later inquiries placed the mortality, when at its maximum, at an even higher figure than this, some estimating it at 1000 deaths daily, while others thought it had attained to 1500 deaths per day. The same report estimates the total cholera mortality in Tehran at between 15,000 and 20,000 but adds that other authorities think that at least 25,000 persons lost their lives. The epidemic spread to the surrounding villages, including those where the embassies and legations usually spend the summer months. Cases occurred in the staff of the Ottoman Embassy and among the attendants of the Shah himself. The sovereign had arranged to leave Tehran for Kazvin but the cases of cholera occurring among his attendants on the day of his intended departure he returned to his summer residence near the capital. The city was largely deserted at the height of the epidemic; the shops and bazaars were closed and all public offices stopped work. Almost no public measures of any kind were taken to control the epidemic. Cemeteries were established quite close to the town but the report quoted speaks of putrid emanations from the bodies of the dead which were presumably unburied or very imperfectly buried. At the date of that report (August 2nd) the deaths had fallen to 40 per day but it was added that with the return of the population to the city and the appearance of the disease in the Jewish quarter a slight rise in the mortality had set in. This increase does not, however, seem to have been maintained and the latest reports from Tehran state that the disease has almost disappeared. It may be added that reports from Russian sources confirm the above facts and figures and add that in Tehran the European colony almost entirely escaped the disease, only three deaths from cholera occurring among them. The severity of the outbreak in some of the villages is shown by the fact that in one village, with a population of 5000, as many as 1500 persons died from cholera. As usual in cholera epidemics the earlier cases were the most severe, many being fulminant in character, causing death in a few hours, but later the attacks assumed a milder form. No one, it is added, who entered the city from the surrounding districts for business purposes escaped an attack.

---

[1] THE LANCET, June 25th, p. 1813.

Details of the cholera epidemic in other parts of Persia are almost entirely lacking. All that can be stated is that at the end of June cholera was present at Shuster, Dizful, Sine (? Sihna), and Kazvin; that on July 6th it was reported from Khanikin, on the frontier, that over 200 deaths daily were occurring at Yer, Jerid, Mehanend, and Hamadan-Serai and that the disease had appeared at Ratada; that on July 8th cholera had *not* reached Tabriz (on the authority of the Turkish vice-consul in that town); that on July 19th the outbreaks at Sultanabad and Burujird were stated to be increasing; that on July 31st the Turkish embassy at Tehran telegraphed that cholera was prevalent ("la maladie règne") at Shiraz, Ispahan, and Meshed; that on August 8th Bushire was reported to be still free from the disease though cholera was prevalent at six hours' distance from that port; and that on August 16th the Russian delegate to the Constantinople Board of Health informed the board that some cases of cholera had occurred at Resht, Meshed, and Astrabad.

From this rapid survey it will be seen that cholera has spread over a very large portion of the Persian kingdom. It is, or has been, present at Meshed in the north-east, at Tehran and Resht in the north-west, and at Shiraz and near Bushire in the south-west.

The fears expressed in some of my earlier letters that the infection would spread to Meshed and the shores of the Caspian have thus been realised but fortunately it does not seem as yet to have extended across the Perso-Russian frontier to Transcaspia; though, as stated at the beginning of this letter a single case has been reported from Baku, on the Caucasian shores of the Caspian Sea. That case was reported by the Governor of Baku on August 4th (July 22nd, Old Style); it was then spoken of as a case of cholera, without any qualifying adjective. The patient recovered and it has since been spoken of as a "suspected" case of cholera. The Russian authorities declare officially that no other case of the disease has occurred in any part of Russia. Owing to the occurrence of this case Turkey imposed a "medical visit" on arrivals from Batum, although no disease existed there, and this port is quite 500 miles from Baku and separated from it by the whole width of the Caucasus. The measure was, however, suppressed a week later.

While the above has been the course of the epidemic in a northerly direction, it has at the same time been spreading southwards and south-westwards from Basra and the Shatt-el-Arab to the Arabian shores of the Persian Gulf and to that little known inland province of Arabia, the Nejd. It will be recalled that by the end of June cholera had appeared at Katif and Dekin; at Darein and Narvet, two villages in the Katif district; and in the province of Katar. No further news was received from here until July 29th, when it was reported from Basra that 11 cases of cholera and 23 deaths had occurred in the villages of Redarin and Naren in the *sanjak* of Nejd and that the disease had appeared at Ajir on the coast. On August 3rd a delayed telegram from Basra gave statistics showing that a very large number of places in the inland province of Nejd and the coast province of El Hasa had been invaded by the disease and that in many it had caused a high mortality. The following are the figures given in this telegram, but it should be added that most of the names mentioned cannot be identified on the best maps of these regions:—

		Cases.	Deaths.

Constantinople, Sept. 3rd.

Looking Back.

FROM

THE LANCET, *SATURDAY*, SEPT. 23, 1826.

[*From our Correspondent.*]

LETTER FROM LEYDEN.

Magni nominis umbra. LUCAN.

The annual expenses of the student at Leyden are high. I was informed, by one of them, that it requires economy to come through the year with 800 guldens, about 74*l.*—a much larger sum than would be necessary in any other than an university town. In the Peterschurch are two monuments which no medical man would omit to see; the one is erected to the memory of Boerrhaave and the other to Camper. Boerrhaave's is an urn of white, placed on a pedestal of black marble: on the pedestal hangs a medallion of white marble, with the [illegible] veri simplex," and in front is the d[illegible] Boerrhavii, Genio Sacrum, natus d.31 Dec. 1668, Denatus d.23 Sep. 1738. The urn is entwined by a wreath of heads, in bas relief, which gives the whole a too overloaded appearance. Camper's monument is simple and neat; his bust in white marble, *à l'antique*, is placed on a pedestal of black; on the front of which is this inscription:—"Peterus Camper," geboren te Leyden, den 11 May, 1722, overleden den 7 April 1789. This bust is said to be a striking likeness of Camper; it was sculptured from his celebrated portrait by Runbard Vinkelis. Camper, although very much respected in Holland, was a very vain man, but his arrogance was almost insufferable after he became a member of the States' Assembly. It used to be a favourite expression with him when pointing out anything he supposed new, "people will always say, that Camper observed this." Boerrhaave was certainly a very rich man, but he did not gain all his wealth by physic; he partook of the commercial spirit of his countrymen, and was at one time a large speculator in wool. His favourite residence was at Lond, just a short distance from Leyden, which he purchased of an Englishman; it was here that he spent so much time in the cultivation of tulips. Brugmann, one of the Professors, is in possession of many of the letters of Boerrhaave; among others is one to a student, who aped Boerrhaave in his slovenly manner of dress. The old gentleman did not like to be mimicked, so he told him, "that although slovenness might become an old man, it was not fitted for a youngling." He was very avaricious, and old Gaubius was still more so; neither of them would give their advice to persons not well known without first having the fees. A nobleman of Mecklenburgh requested Boerrhaave's advice by letter, respecting his wife; he wrote him twice but got no answer. He sent him a third letter, with 100 ducats, and Boerrhaave, in return, told him that his wife must ride. Now as the Mecklenburghers have very fine horses, they understand by riding, exercise *à cheval;* the noble lady was put on the back of a fine roadster, and in a short time was jolted to death. The husband was very wroth, and wrote Boerrhaave a furious letter, but the old physician sent word, that by riding, in Holland people meant sailing on a canal. He had forgotten, however, that there were no canals in Mecklenburgh.[1]

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8464 births and 4989 deaths were registered during the week ending Sept. 17th. The annual rate of mortality i[illegible] d been *20·5, 18·2, and 17·5 per 1000* [illegible] weeks, further declined last week to 1[illegible] lon the death-rate was 15·3 per 1000, while it averaged 17·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·1 in Handsworth (Staffs.), 6·7 in East Ham, 7·1 in Hastings, 8·9 in Walthamstow, 9·0 in Burton-on-Trent, 9·6 in Reading, [illegible] 10·3 in Smethwick, and 10·4 in [illegible]

---

[1] An excerpt only has been transcribed.

highest rates were 24·0 in Walsall, 24·7 in Stockport, 24·8 in Warrington, 25·1 in Hull, 25·5 in Sunderland, 26·1 in Hanley, 27·8 in Salford, and 31·6 in Wigan. The 4989 deaths in these towns last week included 1192 which were referred to the principal infectious diseases, against 2291, 1636, and 1512 in the three preceding weeks; of these 1192 deaths, 949 resulted from diarrhœa, 73 from whooping-cough, 48 from diphtheria, 45 from measles, 39 from "fever" (principally enteric), 33 from scarlet fever, and five from small-pox. No death from any of these diseases occurred last week in King's Norton; among the other towns they caused the lowest death-rates in East Ham, Hastings, Bournemouth, Reading, Handsworth (Staffs.), Burton-on-Trent, Huddersfield, South Shields, and Cardiff; and the highest rates in Hanley, Walsall, Wigan, Warrington, Burnley, Preston, Hull, Sunderland, and Gateshead. The greatest proportional mortality from measles occurred in Walsall, Bootle, and Salford; from diphtheria in Hanley; from whooping-cough in Great Yarmouth, Bristol, Wigan, and Barrow-in-Furness; from "fever" in Hull; and from diarrhœa in Ipswich, Hanley, Wigan, Warrington, Burnley, Hull, Sunderland, and Gateshead. The mortality from scarlet fever showed no marked excess in any of the large towns. Three fatal cases of small-pox were recorded in Oldham, one in Preston, and one in Gateshead, but none in any other of the 76 large towns. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals on Saturday, Sept. 17th, was five, against 13, nine, and eight on the three preceding Saturdays; one new case was admitted during the week, against none, two, and two in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 1781, 1820, and 1816 at the end of the three preceding weeks, had risen again to 1929 at the end of last week; 340 new cases were admitted during the week, against 263, 266, and 234 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 101, 108, and 129 in the three preceding weeks, further rose to 141 last week, and were 12 in excess of the number in the corresponding period of last year. The causes of 49, or 1·0 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner.
All the causes of death w
Bristol, Nottingham, Salf
castle-on-Tyne, and in 43

in-Furness, Rotherham, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16·2, 16·0, and 15·7, per 1000 in the three preceding weeks, rose again to 16·5 per 1000 during the week ending Sept. 17th, but was 0·5 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·0 in Paisley and 14·3 in Aberdeen to 17·8 in Glasgow and 21·5 in Perth. The 547 deaths in these towns last week included 69 which were referred to diarrhœa, 13 to whooping-cough, eight to "fever," seven to diphtheria, three to measles, two to scarlet fever, and one to small-pox. In all, 103 deaths resulted from these principal infectious diseases last week, against 97, 100, and 86 in the three preceding weeks. These 103 deaths were equal to an annual rate of 3·1 per 1000, which was 1·0 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 56, 58, and 52 in the three preceding weeks, rose again last week to 69, of which 42 occurred in Glasgow, nine in Dundee, four in Edinburgh, four in Aberdeen, four in Paisley, three in Leith, and two in Greenock. The deaths from whooping-cough, which had been 24, 26, and 17 in the three preceding weeks, further declined to 13 last week, and included six in Glasgow and four in Edinburgh. The fatal cases of "fever," which had been six and five in the two preceding weeks, rose again last week to eight, of which two were registered in Glasgow, two in Dundee, and two in Greenock. The deaths from diphtheria, which had been one, four, and five in the three preceding weeks, further rose to seven last week, and included two in Glasgow, two in Edinburgh, and two in Greenock. The three fatal cases of measles showed a decline of two from the number in the preceding week, and included two in Glasgow, where the death from small-pox also was recorded. The two fatal cases of scarlet fever corresponded with the number in the preceding week and both occurred in Aberdeen. The deaths referred to diseases of the respiratory organs in these towns, which had been 55, 53, and 58 in the three preceding weeks, declined again to 55 last week and were 16 below the number in the corresponding period of last year. The causes of 17, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·5, 19·9, and 20·8 per 1000 in the three preceding weeks, declined again last week to 16·8 per 1000. During the past four weeks the death-rate has averaged 20·3 per 1000, the rates during the same period being 16 5 in London and 14·5 in Edinburgh. The 122 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 29 from the number in the preceding week and included 17 which were referred to the principal infectious diseases, against 49, 29, and 32 in the three preceding weeks; of these, 14 resulted from diarrhœa, two from "fever," and one from diphtheria, but not any from small-pox, from measles, from scarlet fever, or from whooping-cough. These 17 deaths were equal to an annual rate of 2·3 per 1000, the death-rates last week from the principal infectious diseases being 2·7 in London and 1·7 in Edinburgh. The fatal cases of diarrhœa, which had been 26 in each of the two preceding weeks, declined last week to 14. The 122 deaths in Dublin last week included 43 among children under one year of age and 20 among persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a considerable decline from the respective numbers registered in the preceding week. Four inquest cases and two deaths from violence were recorded; and 45, or more than a third, of the deaths occurred in public institutions. The causes of two, or nearly 2 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: J. C. Ferguson to the *Formidable*, on recommissioning; W. Bowden, D.S.O., to the *Boscawen*: and F. A. Brice to the *Revenge*. Staff Surgeons: P. H. Boyden to the *Prometheus*, on commissioning; T. W. Philip to the *Excellent*; and G. A. S. Bell to the *Breton*. Surgeons: P. L. Crosbie to the *Formidable*; R. M. Richards to the *Vulcan*; and J. C. Rowan to the *Fire Queen*.

Inspector-General of Hospitals and Fleets Duncan Hilston, C.B. (retired), has been appointed Honorary Physician to His Majesty, in place of Inspector-General of Hospitals and Fleets Dugald McEwan, deceased.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel F. B. Maclean joins at Woolwich. Major C. A. Lane is held in readiness to embark for Ceylon. Captain J. L. Jones is held in readiness for service in Ceylon. Captain S. W. Sweetnam proceeds from Colchester to Weedon for duty and assumes medical charge of the troops and Station Hospital. Lieutenant F. M. M. Ommanney is appointed Medical Officer, 6th (Somaliland) Battalion the King's African Rifles. Major J. Fayrer is to be appointed Medical Officer of the Duke of York's Royal Military School, Chelsea.

Lieutenant D. D. Paton, from Seconded List, to be Lieutenant (dated Sept 1st, 1904).

VOLUNTEER CORPS.

olunteer Battalion the
J. P. Atkinson to be
d Sept. 17th, 1904).

1st Volunteer Battalion the Gordon Highlanders: The undermentioned Surgeon-Captains to be Surgeon-Majors:—G. M. Edmond (dated Sept. 17th, 1904) and G. Williamson (dated Sept. 17th, 1904).

The Tibet Expedition and Lhasa Treaty.

Colonel Younghusband's difficult mission, which called for the exercise of no little diplomatic skill, judgment, and courage, has been admirably conducted to a successful issue. The expedition has been of a very interesting and novel, but nevertheless of a very trying, character owing to the geographical obstacles that had to be overcome and the diversities of climate that had to be encountered. The military force on the march to Lhasa suffered to some extent from dysentery, hill diarrhœa, and sickness, and the transport difficulties at the altitudes which it traversed were immense, entailing very arduous work on the army medical, sick transport, and hospital services. The *Journal of the Royal Army Medical Corps* for the present month contains a short but excellent article by Major A. R. Aldridge, R.A.M.C., on the subject.

The date of the departure of the British force for India has been officially and definitely fixed for Sept. 23rd. Snow has already fallen on all the passes on the road to Gyang-tse, as well as at Gyang-tse itself. The temperature along the shores of Lake Palti is 12° lower than it is at Lhasa. The force has been able to purchase locally a certain number of blankets but the men are without fur coats and other articles of clothing which were found essential last winter. Store depôts have been erected at various points along the route to be taken by the mission on its return march. The number of native followers accompanying the troops on such occasions is always relatively very large.

The late Sir William Flower.

It is not perhaps generally known that the late Sir William Flower served as an army surgeon with the 63rd Regiment during the Crimean war where he and his colleagues regularly and successfully administered chloroform in their surgical operations despite the warning contained in an official memorandum issued by Sir John Hall, the medical chief of the army in the field, at the beginning of that war. Army medical officers happily did not share the views of their chief and used this anæsthetic with the best results, but chloroform was not at the time of the Crimean war so generally known—at any rate, in the experience of war surgery.

Recreation Grounds for Soldiers and their Children.

We understand that the Army Council has under consideration the provision of recreation grounds for soldiers at barracks and other quarters where such provision does not already exist and a general inquiry is being made into the matter. While on this subject might it not be well for the Army Council to consider also the expediency of providing something in the shape of a playground for the children of a big barrack population instead of allowing them to wander about indiscriminately in the barrack yards in the vicinity of surface drains and gratings into which they may be often throwing stones and dirt by way of pastime?

The War in the Far East.

After a comparatively short lull following a period of almost continuous hard fighting which made rest on the part of the exhausted belligerents absolutely essential, but during which both sides have been heavily reinforced, active operations have again recommenced. A big and decisive battle somewhere in the vicinity of Mukden is fully anticipated to occur shortly. In the rush of events there has been neither time nor opportunity to do more than roughly estimate the casualties and losses. We have learned little or nothing of the medical aspects of the campaign nor are we likely to do so in present circumstances. From all we read and hear a very large number of Russian wounded (in addition to those at Mukden) have been congregated in Harbin; all the buildings are occupied as hospitals and the town has, in fact, become a vast hospital. The Russian headquarter staff admit that their losses from August 26th to Sept. 8th before Liaoyang were two generals, 256 officers, 21,809 soldiers killed, wounded, or missing, and 133 guns. According to a telegram from St. Petersburg, published in the *Echo de Paris*, there are over 35,000 wounded at Harbin under treatment. *If* this be the case it is no wonder that the town is represented as being one vast hospital. It is perplexing to form any idea of how this multitude of patients are fed—to say nothing of their being treated. The weakness of the Japanese in cavalry to follow up their enemy in the retreat from Liaoyang no doubt saved General Kuropatkin's army from more disastrous losses. In addition to the exhaustion following the marches and battles both the Russian and Japanese armies suffered from a failure in their food-supplies after Liaoyang—a greater difficulty to be surmounted in the case of the Russians on account of their longer distance from their base and their dependence on a line of railway, whereas the latter, having command of the sea, are much nearer home and can always make use of any available rivers and waterways. The difficulties in the way of transporting, accommodating, and feeding the sick and wounded must have been well-nigh insurmountable in the circumstances. With regard to the stores of all kinds captured at Liaoyang there is an extraordinary and irreconcileable difference between the Russian and Japanese estimates, but the latter are corroborated by lists of the actual numbers alleged to have been captured. It is needless to add that the supplies and feeding of a force and of its hospital population will greatly turn on this point. Port Arthur still holds out and the feeling of the besieged and besiegers is apparently daily growing worse, but we know little or nothing of the number of the sick and the wounded in that garrison or of their sufferings beyond what we may reasonably conjecture to be the case. To add to the internal troubles and anxieties of the Russian Government at the present time the recent appearance of cholera in the chief towns of the Russian Transcaspian district, whence it is feared that it may be introduced into Russia proper by way of the Central Asian Railway and the Volga, must not be lost sight of. Judging by previous experience the appearance of this disease, possibly in epidemic form, may probably be anticipated next spring and summer.

The Russian Viceroy has decorated four medical officers for having carried wounded from the fighting line under a fire of shrapnel in which two of them were themselves wounded. He said to them: "In the name of His Majesty the Czar I award you a sign of military distinction and thank you for your honourable deeds. Your services are as great and honourable as though done as soldiers. A timely assistance in the firing line enables many of our braves to return the sooner to the defence of the Faith, the Czar, and the Fatherland."

Correspondence.

HOT WEATHER AND FOOD PRESERVATIVES.

To the Editors of The Lancet.

Sirs,—The question raised in my letter of August 21st cannot be dismissed so lightly as Dr. A. S. F. Grünbaum seems to think. Those who like myself have had a considerable experience of out-patient practice in large cities know well that the children of the very poor are largely fed on other things than milk, that milk is often beyond the reach of their parents' means, and that, as the mothers say, "they get a bit of anything that's going." Whether milk was ever much preservatised in Liverpool or not does not affect my argument, for the mortality from infantile diarrhœa in Liverpool has always been high though it has seldom approached the figure recorded this year. But we do know that there have been prosecutions in Liverpool for boric acid in margarine and in cream, and my point is that if the dealers had not *had the fear of* the inspector before their eyes they would have used some preservative in milk and other articles during the period of excessive heat, and that had they done so the rapid putrefaction of the food and the consequent high mortality from infantile diarrhœa might have been to some extent, at least, prevented. Dr. Grünbaum seems rather shocked at my presuming to hold an opinion at variance with the recommendations of the Departmental Committee on Preservatives in Foods, but I plead in extenuation that most of those medical witnesses who were actually concerned with practice among the poor in large cities were by no means inclined to go the lengths advocated by the committee, that opinions expressed by a committee three years ago are not necessarily binding in the light of subsequent experience, and that the Government which appointed the committee attaches so little importance to its recommendations that, although they were made three years ago, no attempt has been made to enforce them by legislation.

In response to my invitation to bring forward a single instance of injury from the reasonable use of boric acid or salicylic acid as a preservative in food Dr. Grünbaum refers me to a case quoted by Dr. E. W. Hope in his evidence before the Food Preservatives Committee. If Dr. Grünbaum considers this case convincing I can only explain it by the readiness with which the scientific mind can be deceived in the face of matters outside the laboratory. At the risk of being tedious I will briefly relate the case. Dr. Hope told the committee (Answers 6841, 6910-12) that a lady complained to him that she had made arrangements with her milk dealer to give him twice the amount he asked upon the condition that he should send her nothing but pure milk. One day her infant was taken violently ill. Nothing had been given it but under her own supervision. She at once went to the milkman and asked what he had been sending and he admitted that he had put some boric acid in the milk on that one day but on no other. Now it is apparent that the case is only "quoted," as Dr. Grünbaum happily expresses it, that it was only hearsay evidence, and that the statement that boric acid was only used on that one occasion was twice hearsay, and that the veracity of its alleged author was not above suspicion. But taking the story as it stands we are not told what were the symptoms in the child, what other food it may have had, nor whether it got well when other milk was supplied. Further, if the boric acid was the cause of the violent illness in the child one would expect to hear of similar cases in other children receiving milk from the same source and to hear of more or less continuous ill-health in children whose parents had made no special arrangements *with regard to the quality of the milk supplied. This* case will certainly not carry conviction to the "unprejudiced observer" and Dr. Grünbaum has not strengthened his case by referring to it. The researches of the Reichs-Gesundheitsamt by no means settle the question and, *pace* Dr. Grünbaum, the conclusions drawn from them have been effectually disproved by Liebreich. The experiments of Tunnicliffe and Rosenheim also are as strong in favour of the innocuousness of boric acid to children as any evidence alleged on the other side.

The distinction Dr. Grünbaum draws between decomposition and putrefaction in food is a purely artificial one. There is no reason to suppose that odourless, almost tasteless, bodies such as boric acid can allow decomposition to take place and at the same time destroy the signs by which it is made evident to the senses. But it is hardly necessary for me to insist on this point, for the medical officer of health of Liverpool has stated[1] that diarrhœa occurs at a time when food becomes rapidly *putrescent.*

The alleged drawback of preservatives that they open the way for dirty and fraudulent practices and make it difficult to teach care and cleanliness to the poor can have but little weight if it be true, as I maintain, that they keep food in a condition fit for consumption which would otherwise have to be thrown away. In a community in which probably 25 per cent. of the people are too poor to purchase enough food to maintain themselves in full health the importance of avoiding all unnecessary waste is obvious. Even if we grant all that has been alleged against preservatives their strongest opponents have not attempted to show that the use of them has ever raised the death-rate to 39 per 1000. I do not hold up the use of preservatives in food as a counsel of perfection. If our slums were abolished and our people were all wise and prosperous there would be less use for them, though I believe that in the case of temperance beverages they will always be needed to supply the place of the alcohol which keeps intoxicating drinks from going bad. What I do maintain is what I stated in my letter of August 21st, a statement which Dr. Grünbaum has not attempted to controvert—namely, that in the conditions under which the poor live in our large cities their food is certain to undergo rapid decomposition in hot weather unless preservatives are employed.

I am, Sirs, yours faithfully,

THC [illegible]

Liverpool, Sept. 10th, 1904.

TO MEDICAL FREEMASONS.

To the Editors of THE LANCET.

SIRS,—May I through the medium of THE LANCET once more appeal to medical Freemasons for their votes and influence on behalf of those candidates for the Masonic charitable institutions who are children of medical men and consequently have special claim on your readers. At the forthcoming election of the Royal Masonic Institution for Boys the "medical candidates" are: D. C. W. Wingrave, aged ten years, son of Dr. V. H. W. Wingrave of St. Albans; B. O. I. Russell, aged eight years, son of the late C. H. Russell, medical officer of health of Southampton; and H. J. Castles, aged nine years, son of the late Mr. K. Castles of Harrington, Cumberland. The "medical candidates" for the Royal Masonic Institution for Girls are: I. M. Sewart, aged eight years, daughter of the late Mr. J. H. Sewart of Lostwithiel; A. M. D'Arcy Sugden, aged ten years, daughter of the late Mr. D'Arcy Sugden of Buckfastleigh, South Devon; and L. Fausset, aged ten years, daughter of the late Mr. J. D. Fausset of Fleetwood. Votes for any of the above will be thankfully received by myself or our treasurer, Dr. J. W. H. Eyre, Wandle House, Wandle-road, S.W.

I am, Sirs, yours faithfully,

HAROLD S. SINGTON,

Secretary, St. Luke's Medical Lodge of Instruction.

44, St. Mary's Mansions, W., Sept. 16th, 1904.

THE COMPARATIVE INTELLECTUAL POWERS OF THE TWO SEXES.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 10th, p. 777, you did me the honour to mention my paper read at the meeting of the British Association and dealing with the progress of schoolboys and schoolgirls. I found by my observations that in elementary schools the balance of proficiency, even in arithmetic, inclines to the side of the girls. In this respect you express the opinion that "the intellectual superiority of girls ...... is so unexpected and so entirely opposed to the teaching of the world's history that we naturally turn to other possible sources of explanation. ...... The vulnerable features of these statistics ...... is that they refer to a period of life which both in boys and girls is subject to disturbances, sexual and otherwise. These disturbances ...... may offer some explanation of the fact that nearly the whole work of human progress can be traced to the maturer activities of the male and not of the female intellect." As my own opinion coincides nearly entirely with yours it seems that you had before you only a short excerpt of my paper which in reality puts forth the same views that you expressed. I enclose the official abstract of my paper by which you may convince yourself that what I suggested is the following: In childhood girls learn better than boys, probably in consequence of the quicker physical development of the female sex, but since not only in sciences but also in poetry and (with exception of the stage) in arts, the great work of human progress has been accomplished by the male sex, one is obliged to suppose that with the age of ripening the female intellect develops itself more slowly than the male one.—I am, Sirs, yours faithfully,

Dr. JOSEPH DE KÖRÖSY,

Budapest, Sept. 19th, 1904. Director of Municipal Statistics.

⁂ We regret that imperfect information should have led us to imply that Dr. de Körösy had not appreciated the difficulty to which we referred, but we are happy to see from his letter and from the official report which he incloses that his opinion coincides with our own.—ED. L.

OBTURATOR HERNIA FOLLOWING MUSCULAR EFFORT.

To the Editors of THE LANCET.

SIRS,—I am sending notes of the following case on account of its rarity.

[illegible] years, when at work [illegible] pain in the abdomen. [illegible] when he walked home and was seen by a colleague; he complained of great pain. Magnesium sulphate and calomel were administered, with the only result of causing vomiting. The vomiting continued the whole of the next day, notwithstanding that morphine was administered hypodermically. On the 29th at 11 A.M. I saw the patient. He was in great pain and begging for relief; he was cold and almost pulseless. He was removed to the West Cornwall Miners' and Women's Hospital, Redruth. Strychnine was given and injections of brandy and coffee also to revive him. At 2 P.M., after lavage of the stomach, Dr. W. Blackwood administered ether and with the assistance of Dr. F. Hichens I opened the abdomen to find a hernial sac free in the abdomen. On nicking the neck several inches of dark maroon-coloured gut were liberated and some dark fluid was evacuated from the sac. The patient did not rally from the shock and died at 9 P.M., notwithstanding stimulants, &c., to reduce the shock. The case appeared to be the reduction *en masse* (spontaneously) of an obturator hernia. On passing the finger into the empty sac it went up to, but not through, the obturator foramen and the only explanation I can give is that the great peristalsis caused by the purgatives must have given rise to the condition. I am, Sirs, yours faithfully,

Camborne, Sept. 13th, 1904. JOHN H. TONKING.

DEATHS UNDER CHLOROFORM AND THEIR PREVENTION.

To the Editors of THE LANCET.

SIRS,—There are two points in connexion with the death under chloroform which you record in your issue of Sept. 17th (p. 841) that I think are worthy of comment. The first is the fact that the patient died within seven minutes of the commencement of the inhalation, and the second that he died immediately after being lifted on to the operating table from the bed, or lorry? With regard to the first point Dr. F. W. Hewitt on p. 342 of his most admirable work on "Anæsthetics" draws attention to the fact that a large proportion of deaths occurring under chloroform take place within a few minutes of the time that the administration is started and he instances 75 fatalities in 68 of which the patient died within the first 15 minutes. I have before me at the moment of writing details of other 63 deaths under chloroform, all of which occurred during one year in the United Kingdom, and in 60 of these the patient died within a few minutes of the commencement of the administration of the chloroform, several after a few inspirations. With these figures facing me and with my own personal experience of practical anæsthetics I find it impossible not to differ from Professor A. D. Waller[1] in the view which he has expressed that deaths under chloroform are generally caused by overdose. I am disposed to think that overdose—that is, imbibition of an excessive and toxic amount of chloroform—is a comparatively rare cause of death and that when it occurs the condition produced by this overdosage is often a remediable one if proper measures are promptly adopted.

The most frequent and usual cause of death under chloroform—and no one with his eyes open can question it—is syncope arising from two ordinary physiological actions of chloroform on the human economy which are: (1) to produce vagus excitability (Embley); and (2) to abolish the vascular mechanism which compensates for the mechanical effect of gravity (Leonard Hill). When death occurs at or immediately after the moment of lifting a patient from the bed to the operating table during chloroform anæsthesia, as in the case you record, this latter action will in many cases probably be the causative factor and no overdose is necessary. When, on the other hand, death occurs before complete unconsciousness from "fright syncope" (of which numerous instances are recorded) and in cases where the first incision is made during imperfect anæsthesia excitation of the vagus is probably the predominating factor. Further, when a patient is attacked by syncope, whether he has been chloroformed or not, restorative measures are seldom of any avail. On the other hand, most anæsthetists, especially those who have to do with the instruction of students or post-graduates, will be able to recall cases where the patient "had a little too much," stopped breathing and turned blue, or even pale, but active restorative measures being applied, no great difficulty was found in getting rid of the excessive dose or, at any rate, restoring animation.

Personally I have never seen a case of chloroform syncope but two cases occurred recently in the hands of friends of mine. I am quite confident that in neither of these instances was any overdose of chloroform administered and such deaths cannot be avoided by the use of Dubois's or Harcourt's dosimetrical apparatus. However interesting the investigations of the British Medical Committee may be from the physiological side one is somewhat at a loss to see what practical outcome of value we can expect to result from them. The chief advantage claimed for chloroform as opposed to ether in the past has been its handiness and if we handicap it with an apparatus of an extremely fragile nature, like Harcourt's, or with one weighing a couple of stones, like Dubois's, then surely one of the strongest claims of this anæsthetic to favour has vanished. Moreover, it is impossible to suppose, even were the fact absolutely established that overdose with either of these ingenious apparatus was impossible, that the country practitioner or the metropolitan anæsthetist would go to his cases with one of these apparatus in his bag and use it as a matter of routine. Time and space have a lot to do with practical surgery and the hospital theatre cannot be turned into a laboratory nor the medical man into a beast of burden. In the case to which my friend, Dr. W. J. McCardie, referred at Oxford[2] 15 minutes were required to "dull or abolish the lid reflex with a 1 per cent. vapour and 12½ minutes with a 1½ per cent. vapour." Where is the surgeon who will stand by quietly waiting during these periods on a busy hospital "field day" in the year 1904? Safety in the administration of chloroform and a diminished death-rate under anæsthetics are not to be found in the employment of dosimetrical apparatus, "blow-through" or otherwise. In my humble opinion it will be found in quite another way and that is in the rapid induction of anæsthesia in all possible cases by means of a different agent from chloroform—viz., ethyl chloride, which in certain cases can be followed with advantage by ether. When once unconsciousness is induced and anæsthesia present by means of this agent or these agents the dulled sensorium and stimulated cardio-vascular system may be subjected to the excitant and depressant action of chloroform, on them respectively, not with absolute freedom from risk of overdose it is true, but with the comforting knowledge that the patients will not suddenly "turn pale and die" from syncope "after the first few breaths of the anæsthetic." Risk of overdose during the operation may surely be eliminated if a reasonably skilful and careful administrator be employed.

It may be considered bold for me to make this statement but I do so on the strength of a personal experience of considerably over a thousand cases of ethyl chloride narcosis and ethyl chloride sequences during the past year and I believe my favourable opinion of ethyl-chloride-ether-chloroform sequence is shared by Dr. McCardie whose experience with the first-named anæsthetic is unique. During this time I have had all classes of patients in my hands, from the hysterical nervous female to the whisky saturated alcoholic male, and all have been negotiated with ease—at any rate, with ease as regards the first 15 minutes. The most striking thing is the complete absence of anything but quite momentary struggling in alcoholic patients of the worst type. Before they have time to get violent voluntary movement and involuntary "excitation movements" are paralysed and they settle down into an even, if at times somewhat stertorous and noisy, anæsthesia. With ethyl chloride properly administered unconsciousness is obtained in from 15 to 20 seconds, anæsthesia in less than a minute, and profound ethyl-chloride-ether anæsthesia in two and a half minutes. Ethyl chloride as an "introducer" to chloroform anæsthesia is certainly worthy of the attention of the profession. The progress of this anæsthetic during the past two years has been remarkable and will, I sincerely hope, continue. Were it generally realised that practically nothing but a Clover's inhaler or an Ormsby is required to administer it satisfactorily I think it would be more widely used *per se* than it is, but the continual "hatching" of new "special" inhalers for the drug, which are turned out at the rate of rather over one a week, tends to create the impression that the administration is a difficult matter and a very special apparatus necessary, adding to the bulk of the practitioner's armamentarium. When every medical man gets to know that the Clover which he already possesses, or ought to possess, can for a most trifling outlay be adapted for an ethyl-chloride-ether inhaler by any instrument maker he will be more likely to employ ethyl chloride for brief operations where the use of chloroform is unnecessary, if not quite unjustifiable. In this way, eventually, I think, will the present discreditable death-rate under anæsthetics, to which Professor Waller has so eloquently drawn attention, be very sensibly reduced and painful incidents such as you have just recorded be avoided.

PHIMOSIS AND HERNIA.

To the Editors of THE LANCET.

SIRS,—In connexion with the causal relation between phimosis and hernia raised by Dr. H. Lyon Smith in his letter in THE LANCET of Sept. 17th, p. 858, permit me to say that from my experience at the City of London Truss Society I can fully endorse Mr. E. M. Corner's belief that phimosis has but little force in producing a hernia. The essential causes of inguinal hernia in young infants, male or female, are a patent processus vaginalis and distension of the intestines with gas. The more a child cries or strains, provided there is no open peritoneal pouch, the less likely it is to develop a hernia, for the arching fibres of the internal oblique and the transversalis are thus strengthened and effectually close any weak spot there is. Distension is nearly always due to improper food. Severe phimosis is often seen without hernia. Hernia does not appear to be more than ordinarily frequent in boys with [illegible] in inducing descent of the bowel into a sac already in existence I am perfectly sure that circumcision will not of itself cure such a hernia, though, as Dr. Lyon Smith points out, the application of a truss with circumcision might. Careful attention to errors in diet and the application of a truss are much more likely to be the means whereby cure is effected. Circumcise those cases in which it is needful, but do not neglect proper treatment for the hernia by truss or operation.

I am, Sirs, yours faithfully,

Harley-street, W., Sept. 19th, 1904. W. MCADAM ECCLES.

THE TREATMENT OF HÆMORRHOIDS AND ALLIED CONDITIONS BY OSCILLATORY CURRENTS OF HIGH TENSION.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 10th, p. 793, Mr. P. Lockhart Mummery seems to assume that the method of treatment first described by Professor Doumer and adopted by myself with results as given in a recent paper is based upon nothing more solid than empirical grounds. I am bound to say that such a statement is entirely inaccurate and could not have been made by anyone who had taken the trouble to consult the literature of the subject. I may also remind him that the mode of treatment which he describes as "new" has been before the profession for seven years and has formed the subject of an already considerable number of papers in continental and American medical journals.

It is quite true that we do not know everything concerning the physiological action of these oscillatory currents; the same might be said with equal truth concerning a great many of the remedial agents in common use. I might even go further and declare that the employment even of empirical measures by trained observers may not be altogether unjustifiable. In the present instance, however, I have no such position to defend. The idea of applying high-tension currents to fissures and allied conditions is based on sound physiological and pathological knowledge. We know that these currents have the property of abolishing the excitability of sensory nerve endings and also of removing the conductivity of motor nerves. Without going any further into physiological questions we may find here ample justification for applying an agent possessing such powers to the treatment of sphincter fissure. There we find an exaggerated sensibility of the sensory nerve endings, together with spasm of the sphincter muscle fibres. On theoretical considerations, therefore, the application of high-tension oscillatory current is plainly indicated and in my opinion the clinical results obtained are as satisfactory as one could wish.

I quite agree with Mr. Mummery that the haphazard use of electricity as a remedial agent by those who are untrained in methods of accurate physiological observation is undesirable. It is true that a certain class of patients exists which revels in complicated and impressive instrumentation but such will not find their ideal in the consulting-room of anyone who has at heart the serious application of electro-therapeutic measures. Instrumentation may be necessarily complicated but this is a question which bothers the physician only and need in no way concern his patient.

I am, Sirs, yours faithfully,

Devonshire street, W., Sept. 20th, 1904. T. J. BOKENHAM.

AN EASY METHOD OF OBTAINING EXFLAGELLATION OF THE MALARIAL PARASITE.

To the Editors of THE LANCET.

SIRS,—Having till recently failed to get exflagellation in crescent infection I have lately used a method which has proved both simple and very efficacious. This consists in mounting a drop of blood of the usual size on a slide wetted with ordinary cold water held at an angle so that no excess remains. This is quite easily done by a brush or with the finger and the least possible quantity of water is sufficient. The blood is not otherwise "mixed" with water. The red blood corpuscles no longer show a tendency to form rouleaux and the process of exflagellation is the more easily observed. The red corpuscles do not undergo any notable alteration but the leucocytes become a good deal more refractive. [illegible] method of breathing on the [illegible] xflagellation in the first three [illegible]. the first case of tertian fever with gametes was also successful. Tertian fever is common enough here. Since writing the above I have to-day had a case of quartan fever with abundant rosettes in which well-marked exflagellation was seen.

I am, Sirs, yours faithfully,

J. CROPPER, M.D. Cantab.

Ramallah, Palestine, Sept. 7th, 1904.

BULLET WOUNDS OF THE BRAIN.

To the Editors of THE LANCET.

SIRS,—Referring to my paper on a case of the above in THE LANCET of Sept. 17th, p. 825, my attention has recently been called to a somewhat similar case published by Mr. A. E. Barker in THE LANCET of Dec. 2nd, 1899, p. 1508. In this case the bullet entered the hard palate and lodged "in the centre of the brain" one and three-quarter inches from the surface of the skull. Lateral and antero-posterior skiagraphs were taken and the bullet was successfully removed by Mr. Barker 69 days after the injury. I stated in my paper that I had not been able to find a case where the bullet had been removed from the depths of the brain on the results of x-ray localisation.

I am, Sirs, yours faithfully,

Cardiff, Sept. 21st, 1904. WILLIAM SHEEN.

TRAVELLING IN EGYPT.—Messrs. Thomas Cook and Son have just issued their new programme of arrangements for travelling in Egypt, by which it appears their steamers will commence to run between Cairo and the First Cataract in November and continue until the middle of March, with connecting steamers between the First and Second Cataract. A new and interesting feature is the arrangement of combined bookings by Messrs. Cook's steamers and the Egyptian and Soudan Railways, enabling tourists with only limited time at their disposal to make their visits to Upper Egypt more rapidly than can be done by using the steamers only. Tickets will be issued to Khartoum and Gondokoro. The facilities afforded to the travelling public for inspecting the wonderful remains of ancient civilisation which adorn the banks of the Nile are now greater than ever, and with luxurious hotels, not only at Cairo, but at Luxor and Assouan, there is every probability that Egypt, with its incomparable climate, during the coming winter will receive a larger share than ever of the health- and pleasure-seeking public.

MEDICAL NOTES FROM THE FAR EAST.

The following notes are from the pen of a special correspondent who has been making a tour round Korea, North China, and Japan. He visited Seoul, Chifu, and Tientsin and from this last city went to Peking, at which place the following notes commence.

Peking, July 20th.

A brief visit to Peking, three and a half hours up the line, has been of more general than medical interest. Here are legation guards of the eight nations, Russians and Japanese included, and in the British legation is the fine Chinese building used as a military hospital for the British guard, four of whom were in-patients and of no professional interest. Dr. G. D. Gray from Central Africa, as legation physician, has succeeded the late Dr. Wordsworth Poole, whose work in the siege and subsequent death from typhoid fever are recorded on one of the several pathetic and exceptionally well-written brass epitaphs in the legation chapel. Dr. G. E. Morrison, the *Times* correspondent, is of course one of the best known medical men in Peking and happens to be at home—an exception rather than the rule with him—but his narrative has mostly been non-medical and for his thrilling and varied medical experiences we must ask him to hurry up and to publish his Reminiscences himself. But thanks to him I have had the privilege of seeing and hearing of the excellent work being done by medical missions in the city. The Americans have a brand new hospital, up to date in all respects, but I have only had time in pelting rain to visit the hospital of the London Missionary Society, instituted in 1861 and now for four years past managed by Dr. T. Cochrane. In 1898 and 1899 as many as 30,000 visits were paid by out-patients each year to the hospital. Then came the Boxer outbreak. But last year confidence began to be restored and there were 20,000 attendances with 124 in-patients. It is a fine example of a struggle with adverse circumstances and, despite the drawbacks of extemporised buildings and half-trained assistants, the success of laparotomies, lithotomies, and other major operations without a single death is remarkable. Now Dr. Cochrane has made a bold move and is building a new hospital and medical school, complete with lecture rooms, laboratories, and residential rooms for Chinese students. The main block of this fine building is now nearly finished; the whole will cost 50,000 taels (£6000), towards which the Dowager Empress has made her first subscription to a foreign benevolent institution of 10,000 taels. It is noteworthy that the hospital has of late years been entirely self-supporting, local subscriptions making up the difference between the expenses and the receipts from patients, the latter being obliged, except in case of destitution, to pay two sens a visit to prevent the natural tendency of the Chinaman on seeing a drug-shop to feel ill or to lay in a store of medicines against the time when he may feel ill. The building of this new college, however, calls, of course, for funds, and few better objects of philanthropy could be devised, for it is only by educating the intelligent Chinese in a subject so obviously beneficial as European medical knowledge that we can hope to make them appreciate, respect, and hanker after friendship and intercourse with European nations. The only case of special interest that I saw was that of a court eunuch, admitted for some other complaint than that of cicatricial stricture or stone from which they usually suffer. Mutilated, of course without chloroform, at the age of 15 years in order that he might receive employment about the court and so obtain influence for his family, this man had the voice, the pubic hair, and the general secondary characteristics of a man, with a somewhat myxœdematous fulness of the skin, and his genitalia had been so completely removed as to leave only an opening to the urethra just below the pubes. The common results are a stricture so fine as to give rise to great difficulty in micturition and the finest thread-like stream, for which operation is often sought and carried out without great difficulty. A perineal urethrotomy is often the best form of treatment. Mention may also be made of a beggar-lad who was admitted for the loss of both feet from frost-bite and who was saved from death in the streets and the ravages of dogs by being admitted into hospital; the result being a couple of useful stumps.

Shanhaikwan, July 22nd.

A 12 hours' run brought me yesterday evening to this station, where the fortunate traveller may spend the night with the hospitable 30th Punjabis, and the unfortunate may with difficulty find a room in the hotel. It is another military menagerie, with the difference in the absence of the Russian detachment, whose officers were very popular with our Indian mess until they were withdrawn. Occasional brawls occur and only a few days ago a couple of Frenchmen and several Japanese lost their lives in such a quarrel. At Shanhaikwan the Great Wall of China, built in vain to keep out the Tartars and Mongols, ends in the sea, and now from the top of it may be seen a party of Sikhs practising flag-signalling. In 1900 its forts were dismantled and their modern guns were sent home to Europe by the Powers, who have now agreed to guard the line in sections. Two stations after leaving Taku are garrisoned by British detachments; the last few stations before arriving here are manned by Japanese. An hour back down the coast is Peitaiho, the fashionable watering-place of North China, and between that and here is the small port of Chingwangtoo, of considerable importance because it remains ice-free throughout the winter, whereas Taku is frozen up for three months. The 30th Punjabis here are between 700 and 800 strong. During their two years in the station 40 men have been invalided with tubercle. They are occupying the same barracks as were tenanted by the 4th Goorkhas who similarly were severely affected by tubercle until they were put into good barracks in India last year, since when they have been free. These barracks at Shanhaikwan are often two feet under water; even now the surface water is only three feet below the soil. The buildings are very unhealthy and rent is all the time being paid for them to the Chinese owner. A good site and a good supply of ready-made bricks are close at hand of which both Germans and French have readily availed themselves. Many memoranda have been sent in on the subject but still nothing has been done and the soldiers continue to be invalided from tubercle. It is hoped that the return of Colonel Macpherson from the front will be followed by improvement in all these serious defects, which otherwise would be wholly unpardonable and a national disgrace.

Niuchwang, July 25th.

Another 12 hours' run in a far less comfortable train brings me to Yingkau railway station on the right bank, or neutral side, of the Liao-ho; on the left is Yingkau, or the treaty port of Niuchwang, with 70,000 Chinese inhabitants and a foreign settlement administered by the Russians. Three miles up the river on the left bank is Russiatown; 30 miles up is old Niuchwang, conceded by the wily Chinese, who drew up the Treaty of Tientsin in 1867 and thought, rightly, that we did not know that the so-called port which they were throwing open to us was 30 miles up the river and of no use for our purposes. But might appears to be the chief form of right recognised by Europe in her sordid dealings of the last 60 years with China and so we have the prosperous port of Niuchwang at the mouth of the chief river of North China.

Plague is not infrequent here. Last year there were estimated to be 1000 cases between August and December; about 40 of the patients recovered in hospital. There were probably many more unreported cases, but those given were enough for the port to be declared infected. The English medical officer to the administration, Dr. C. C. de B. Daly, is at present away on leave, and his work is being done by a missionary of the Scotch Presbyterian Church, Dr. Bander, whom I found assisting Dr. Brown of Chang-tu-fu to remove a cataract. There appears to be little typhoid fever here but a good deal of tubercle, especially of the glands and the bones. The Red Cross hospital of 40 beds was founded in 1894 by subscriptions mainly from the wealthy Chinese of Shanghai, who subscribed $10,000 (£1000) in the first day and have sent generous subscriptions since for the medical and general relief of their poorer countrymen. The use of the hospital, which is well stocked in every respect, was offered to both Japanese and Russians, both of whom have refused all offers of help, and the hospital is therefore used as a general civil hospital for the poor of Niuchwang. There are no trained nurses.

There have recently been about 1500 Russian troops in and about this port but there appears at no time to have been any provision on a large scale for sick and wounded. A report was recently sent home by a correspondent that hundreds of Russians were lying here sick and wounded without any medical, nursing, or other attention and that the Russian authorities refused to allow even Dr Bander and others to give their services I can only imagine that either the correspondent was mis stating facts or else that a certain number of wounded may have been brought in here for a few hours and were awaiting removal by a hospital train A foreign military attaché, just down from Liaoyang, was giving me yesterday the results of his special inquiries into hospital arrangements, on which he has reported at length to his Government The dearth of medical arrangements on the Russian side appears to have been much exaggerated Their army medical service is limited in number and function; they supply, it appears, only the regimental medical officers and the staff of the bearer companies and officers attached to the personal staff of each general All the hospitals and hospital trains are supplied by the Red Cross which plays a rôle of even greater importance than the Red Cross of Japan Almost every provincial government in Russia and Siberia and many wealthy personages, both of royal blood and in the commercial world, undertake the complete equipment and support of a hospital train or hospital and so far as my informant, a layman, could judge they were all not only well but magnificently equipped The trains were furnished with swinging cots on springs, with baths, kitchens, and operating theatre and complete arrangements for a staff of four medical officers, so many nurses, and 36 attendants on each train Indeed, Dr Kanal, the extremely friendly and gentlemanly medical officer, ranking as Lieutenant-Colonel and attached to the administration here, talks with some contempt of the Red Cross superfluities, just as one heard similar complaints against some of the private hospitals in South Africa He speaks, naturally enough, with still greater fluency of the dangerous independence of the Red Cross from the Army Medical Service As with much else in the Russian system there is plenty of it and of the first quality, but it lacks organisation There can be no doubt that the only proper system is that of the Japanese Red Cross which coördinates all [illegible] working directly under the [illegible] ertaking being given that [illegible] be of the same kind only [illegible] Thus, the succour of sick and wounded is made essentially a second consideration to the primary interests of the campaign, that is of the State, and silly jealousies between private and regular medical supplies and aid are avoided. But, to return to the Russian system, there is no doubt that there is an abundant supply of well equipped hospital trains, dating back to the very opening of the Siberian line, when amongst the first appearances were a police wagon and a "sanitary wagon" painted in white with a Red Cross on it And it seems highly probable that any sick and wounded in or around Niuchwang may have depended on the arrival of a hospital train to treat them and to carry them up the line rather than that they should have been deliberately neglected The Russian administrator, M Victor Grosse, tells me himself that the wounded are taken to the junction at Tashichiao or to the base hospitals at Liaoyang and Kharbin, or beyond the border to Chita and Irkutsk, or finally to Moscow, their distributing centre, or to their sanatoriums in the Crimea St Petersburg and Moscow gave a million roubles each for this Red Cross work and included in its staff they have such well known men as Alexandrovsky, head of the Red Cross, and Professor Zoege von Manteuffel professor of surgery at Dorpat, who is now chief of the Red Cross at Tashichiao Amongst others whom I met at M Grosse's was Professor Vussakovitch, professor of bacteriology and pathology at Kieff who was recently working for three months with Haffkine at Parel in India and is now sent out specially to secure the troops against plague and cholera As he says, his position is likely to prove a sinecure, for there evidently is no very serious illness amongst the forces on either side, although it will be realised that the usual plague season here only begins in July or August and dies off in December, and winter again may produce another series of ailments It is interesting, by the way to hear that winter rather than stop the campaign, will prove of unquestionable advantage to the Japanese, for here, where the thermometer falls to 20° below zero, 50° of frost, the country is frozen so hard that the transport can travel freely without hindrance in any direction, a few cases only will occur of frostbite The river itself is always frozen and with care may provide an excellent surface for sleigh traffic Fortunately, these Russian officers are extraordinarily good linguists. Dr Kanal, whose native tongue is Finnish, speaks Russian, French, and English with about equal fluency "What," said the Swedish attache to a Russian cavalry officer, who had just been talking each of these languages and was now talking to a Spaniard, "you talk Spanish too?" "Yes, naturally enough," was the reply, "considering I'm a Spaniard" He was the fine spokesman and gentleman, Prince Jeamé de Bourbon, son of Don Carlos, now a familiar figure in this town But familiar he will be no longer, nor any Russian officer All day long, from 4 A M to 8 P M, on Saturday and Sunday we have been hearing the sound of guns and from the roof top through our glasses watching the shells burst on the hills a few miles south of Tashichiao, from 12 to 15 miles away Chinese reports tell us of casualties in thousands and still yesterday evening the important railway junction of Tashichiao remained in Russian hands But this morning we were awakened with the news that the Russians were at last evacuating the town in earnest and climbing to the roof tops we saw them march out along the street at our foot and away to Russiatown which at 9 o clock went up in flames, a vast cloud of smoke blotting out for us a quarter of the landscape A visit to Russiatown in the afternoon showed us the whole place gutted, not by fire, but by the Chinese, who were still digging away, naked or clothed only in a loin cloth, with unprecedented energy at the remaining coal-heaps, wrenching away doors and windows, and ripping off the roofs of galvanised iron Only the heaps of forage had been burnt and they were still smouldering on The houses represented purely and simply the downfall of Russia, the letting loose, as greyhounds from a leash, of the lowest class Chinese the Yellow Peril without a doubt, from all semblance of law and order At four o'clock the first Japanese scouts arrived, at nine there appeared a troop of 50, and feeling now the impossibility of getting within the Russian lines I am taking the next boat back to Chifu and Shanghai so as to be in time to visit the Japanese

PS *Nearing Shanghai, August 1st* —I have been hearing a good deal about Russian sick and wounded from refugees, 77 arrived on Friday at Chifu from Port Arthur, one recently from Liaoyang was on our boat from Niuchwang One well informed man of affairs from Kharbin is on board this boat, having left Mukden on Monday evening at 5 P M, at which time he is sure the Liaoyang line had not been cut, although he himself *came across to China and* down the Chinese railway from the up country terminus, Hsin min ting, 40 miles from Mukden Apparently there *are* military hospitals in the Russian army besides those under the Red Cross Society, as with us they are nursed by female nurses and are largely staffed by reserve medical men drawn from civil life, who have been excused military service in return for an unpaid liability to be called out in time of war This of course, tells heavily on many of them who have had to throw up their practices and have to support wife and family while only receiving 144 roubles (£14) a month less than half the pay of a civil surgeon in South Africa As with us the military hospitals, except for local private aid, have little beyond the necessaries laid down in regulations, while the Red Cross hospitals are equipped with lavish magnificence This gentleman has himself seen No 20 hospital train, and each is arranged to take some 200 lying-down patients, 400 in all as compared with the 100 that were carried by our five South African trains I am bound to say that with the picture of the latter still fresh in my mind I shall feel sceptical as to the possibility of any train having comfortable accommodation within manageable limits for so many patients until I have seen one myself But the evidence is certainly good The hospital accommodation at Kharbin—one of those extraordinary Russian cities of only four years' growth—is on a very large scale and 21 "barracks"—presumably pavilions—have recently been built for hospital work in addition to 400 for healthy troops My informant himself saw many trainfuls of wounded come in from Tashichiao which he says was only an artillery action From Kharbin the more slightly wounded and sick are shipped on specially fitted out barges up the Sungari River to Blagovestchensk, Nicholsk, Chita, Khabaroff or any other station on the Ussuri line which runs from Vladivostok to Khabaroff Chita especially is becoming a big centre for hospital work and many of the troops have already been able to get back *to the fighting* line. Their spirit is good and there is no doubt that the Russians, even those who are fairly disinterested and those who are opposed to the war, although expecting Port Arthur to fall within six weeks, are convinced that sooner or later Russia must win by force of numbers. With all deference to the *Times* critic there is no getting over the fact that at every ten miles up to Lake Baikal from Russia there is now a crossing station, that 16 pairs of trains can now pass over the line daily, and that in five weeks ending July 22nd the 10th and 17th Army Corps were brought into Kharbin, a force of 110,000 men all told. Horses have to come from Tomsk; but there is abundance of hay and grain in Manchuria itself, which is an astonishingly rich country and is now enjoying an exceptionally good harvest.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Inaccurately Dispensed Prescriptions: Prosecutions.

EARLY in last month two interesting cases were heard at the city police-courts in connexion with the dispensing of medical prescriptions. The first case was that of a druggist named Heath who had been asked by a messenger from the health department to compound the following prescription written by Dr. J. D. McCrindle, assistant medical officer of health:—

Quin. sulph. ... ... ʒ iv.
Ac. sulph. *dil.* ... ... ʒ iv.
Aq. ad... ... ... ℥ vi.
M.
Sig.: A dessertspoonful every four hours as required.

The mixture should have contained 240 grains of quinine sulphate and 240 minims of diluted sulphuric acid. The messenger, a woman, left the prescription and called later in the day for the mixture. The defendant then asked her if the patient was very ill, because, he said, it was rather an extraordinary dose. He charged 2*s.* The woman handed the bottle to Inspector Jones who came into the shop and explained who he was. The defendant then said, "I did not put the half ounce of quinine in; I only put in half a drachm; I thought it was a mistake." On behalf of the prosecution it was urged that it was the duty of the druggist to make up a prescription obviously coming from a medical man without using his own discretion as to the amount of any particular drug which he should put in. It was also pointed out that the price of 23 grains of quinine was only 1*d.*, whilst the price of 240 grains was about 9*d.* Dr. McCrindle, who gave evidence, stated that he should have expected compliance with such a prescription. The defendant gave evidence on his own behalf and said that he should not think of putting half an ounce of quinine into a six-ounce mixture. The ordinary dose they were accustomed to make up was from one to two grains. When the woman called with the prescription he inquired the complaint of the patient and the address of the medical man and he would not make up the prescription until the woman came back and he had made these inquiries. He also stated that he thought that the prescription was too well written to have come from a medical man and concluded that it was a copy. After a long consultation the bench said that they considered the case to be one of the most important ever brought before them. Up to a certain point the defendant exercised a very proper discretion. But he did not go far enough. When he convinced himself that there was something in the prescription which suggested to his mind that there was possible danger to the patient he should have insisted that the name of the medical man was given to him and he might have absolved himself from all personal responsibility by consulting the medical man. The bench did not think that there was any dishonest intention on the part of the defendant but he had been negligent in his duty and they had no alternative but to convict, though they had tried in every conceivable way to discover whether it was possible to justify the action of the defendant. The penalty would be 40*s.* and costs.—The second case was that of Needhams (Limited). In this instance the messenger from the health department called at one of the branches of this firm and left the following prescription to be made up:—

Pot. iodid. ... ... ʒ vi.
Aq. chlorof. ad ... ... ℥ vi.
M.
Sig.. One teaspoonful with a little water three times a day.

The capacity of the bottle supplied by the defendants was only five and a quarter ounces and it contained only 334 grains of iodide of potassium. The dose given on the bottle was one tablespoonful instead of one teaspoonful, as ordered by the prescription. One tablespoonful contained 32 grains, while the dose ordered by the prescription was seven and a half grains. The prosecution complained chiefly of the size of the dose, which would have had injurious effects if taken. They did not suggest fraud but there was gross negligence. Dr. McCrindle in his evidence said that a dose of the size in question would have had a serious effect upon a weakly person. Cross-examining counsel tried to secure an admission that when a preparation was ordered in a six-ounce bottle the usual dose was one tablespoonful, but Dr. McCrindle refused to admit this. For the defendants it was urged that the greatest care was taken in the selection of assistants and that the person who was responsible for the error in question had served his apprenticeship with the firm and that they had never had the slightest complaint about him. There was no intention to defraud the purchaser, for the assistant had actually charged 4*d.* or 5*d.* less for the mixture than he should have done. Messrs. Needham employed Dr. A. Bostock Hill to go round from time to time and have prescriptions made up at their shops with the object of ascertaining whether their assistants were doing their work properly. The prosecution stated that it had been necessary on a previous occasion to caution the firm about carelessness. The bench held that there was no intention to defraud but that there was carelessness and for that the defendants must pay the costs of the prosecution.

Health of Worcestershire: Decline in the Birth-rate.

The county medical officer of health, Mr. G. H. Fosbroke, has recently issued his report for the year 1903. Only two districts in the county have materially increased during that twelvemonth—viz., King's Norton by 3359 and Yardley by 2470. On the other hand, one urban and 17 rural districts have decreased in population during the same period. The birth-rate in England and Wales for 1903, 28·4 per 1000, is lower than the rate for any year on record and that for the county of Worcester is below this, being only 27·9. Last year the rate of Bromsgrove North District, the average for which during the past ten years has been 29·2, was only 26·0, and Dr. C. Kidd, the medical officer of this district, remarks that "the matter is one with which a sanitary authority has little to do directly, it being a social and moral question rather than one of public health." The districts in which the highest birth-rates have prevailed are populated chiefly by artisans. The death-rate for the year is much the lowest as yet recorded for the county of Worcester. The lowest death-rate for any district is that for Malvern, which was 9·7, and this is closely followed by King's Norton with 10·2 and Yardley with 10·8. It will be noticed that the two last-mentioned districts are those in which the increase of population is most marked, so that the decreased death-rate is doubly satisfactory. The county mortality from small-pox has been low during recent years and in 1903 only equalled 0·003 per 1000 of the population. The disease was taken by tramps into seven of the ten districts invaded, which confirms the well-known facts that small-pox is taken by tramps from district to district and that there is practically no power to control those who have been in contact with the disease, if not actually suffering from it. The annoyance caused by tramps who infest certain parts of the county during the pea-picking is great, for they are not only depraved characters but are also fertile sources of infectious disease. Last year there were no less than 32 separate outbreaks of small-pox in the county, but as the local authorities of the districts in which the disease appeared had small-pox hospitals and the officials promptly adopted suitable precautionary measures the disease was quickly stamped out. Had small-pox broken out in Lye and Woolescote or Stourbridge urban or in Halesowen rural districts, possibly this fortunate state of things might not have happened, for there is no hospital accommodation for small-pox in these districts.

Pecuniary Circumstances of Hospital Patients.

Recent negotiations between the West Bromwich Trades Council and the local hospital afford another example of the manner in which hospitals might be abused if some bodies of working men could have their way. The Trades Council in question has made complaints against the medical staff of the hospital because of what it was pleased to call the unnecessary inquiries into the circumstances of the patients made by those members of the staff whose assistance had been sought The reply received from the secretary of the hospital on behalf of its governing body does not seem to have satisfied the Trades Council, for at a recent meeting dissatisfaction was expressed with it and it was urged that working men who contributed so largely to the support of the institution received their tickets for medical treatment from people who were supposed to exercise their discretion in connexion with their distribution Eventually a motion was passed expressing the hope that the distribution of tickets would in future be recognised by the hospital authorities and also that the medical men would refrain from inquiring into applicants' domestic circumstances

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Liverpool Infectious Hospitals Annual Inspection by the City Council

THE members of the hospitals and port sanitary committee, accompanied by other members of the city council, made their annual inspection of the corporation infectious hospitals on Sept 13th The six hospitals visited were the City Hospital South, Parkhill Hospital the City Hospital East, the City Hospital North, Priory road Hospital, and Fazakerley Hospital In the tour was also included a visit to the new hospital in course of erection at Fazakerley which is to cost over £130 000, exclusive of £38 000 paid for land This new hospital is to be a model of construction and equipment Prior to its commencement deputations from the committee inspected the best infectious hospitals in the country and have utilised the information gained in planning the new institution It may have been that this new hospital would not have been deemed necessary for some years to come but for the fact that Parkhill site on which a series of temporary buildings constitute the hospital, may be required at any time by the dock board who are the owners, for dock extension and the corporation is liable at any time to receive notice to quit Such an eventuality would have displaced between 300 and 400 beds which at a time of pressure would be a grave matter for the community The committee is therefore preparing for any emergency, appreciating the fact that the more infectious cases are isolated for treatment the less will be the danger of the spread of disease When the new hospital is finished every requirement imposed upon the corporation in regard to the treatment of zymotic diseases will have been fulfilled and the heavy expenditure in that direction for the past few years is likely to increase for a time The charge on behalf of the various hospitals for sinking fund interest, and maintenance now approaches £70 000 per annum, which is regarded in some important quarters as the limit to which the city ought to be expected to go with its present population The inspection occupied the committee ten hours Everything possible was inspected, including many wards where fever stricken patients were lying All the hospitals are equipped on the most approved modern basis The scrupulous cleanliness and cheeriness of the wards, rendered additionally pleasant by a tasteful display of choice flowers cultivated within the confines of the hospital grounds or obtained from the city parks and gardens, were greatly admired At the end of the day the company, which numbered about 30 and included the Lord Mayor sat down to dinner in the administrative block of the small pox hospital at Fazakerley Alderman Giles (the chairman of the committee) presided Complimentary speeches were made by the chairman the Lord Mayor, Dr E W Hope (the medical officer of health) and others Dr Hope stated that he never recollected the city so free from infectious disease

Hospital Saturday Fund School Collections

The Lord Mayor has received a letter from the secretary of the Hospital Saturday Fund respecting a suggestion which was made to the former some time ago with regard to a collection in the elementary schools in the city The result of the appeal is most satisfactory The teachers of Liverpool took the matter up warmly and have contributed amongst them upwards of £60, which sum has been handed over to the treasurer of the fund The secretary hopes that the collection may become an annual source of income to the fund

Liverpool's Death rate and the Ship Canal Novel Theory

The medical officer of health reported to the health committee on Sept 15th that the death rate in the city was gradually decreasing The total number of deaths registered during the week was 347, as against 378 in the previous week The death rate has now diminished to 24 9 per 1000, as against 37 7 three weeks ago Mr Isaac Turner, a member of the committee, said it was a singular and noteworthy fact that all the towns on or near the Manchester Ship Canal had been afflicted with similarly heavy rates of mortality — Liverpool, Bootle, Birkenhead Runcorn, Manchester, Warrington, [illegible] responsibility for Liverpool's late high death rate The abnormal rate of mortality was not peculiar to a particular part of Lancashire, it was prevalent all over the county

Donations to Local Charities

The treasurer of the Royal Infirmary has received £1000 from Mrs Barrow to endow a bed in memory of her husband, the late Mr James Barrow Mr W P Hartley has sent £500 and Mr Alfred Booth and Mr Edmond Johnston £200 and £100 respectively to the treasurer of the Liverpool Country Hospital for Children

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS)

Pauperism in Swansea

AT a recent meeting of the Swansea board of guardians Mr I T Bircham, the Poor law inspector of the Local Government Board, animadverted upon the large number of cases of medical relief occurring within the union, which amounted last year to 2174 in a population of less than 100 000 He expressed the opinion that sufficient inquiry was not made before an order for medical attendance was given and said that many men would not perhaps consider it necessary to join a sick club or a friendly society if they could readily obtain the services of the parish medical officer when they fell ill Where able bodied men applied for relief for their wives in cases of confinement he advised that the relief should be given in the form of loan and the cost to the guardians subsequently recovered Figures were placed before the guardians showing that the amount of pauperism in Swansea had increased very considerably during recent years During the past ten years the rate of pauperism was reduced in England and Wales 12 per cent, in Wales and Monmouthshire 13 per cent and in South Wales and Monmouthshire 7 per cent, while in Swansea there was an actual increase of 22 per cent, notwithstanding the fact that the increase in the population of Swansea was only to the extent of 5 per cent, or about a third of the increase in the other districts named

Rhondda Health Report

The annual report of the medical officer of health of the Rhondda urban district is always of interest, relating as it does to a locality of recent growth with an industrial population of about 120 000 persons The birth rate in 1903 was 40 9 per 1000, which was the average rate for 25 years past The death rate in 1903 was 16 7 per 1000, a lower rate than has been recorded for 20 years The average death rate in the ten immediately preceding years was 20 3 per 1000 Dr J D Jenkins (the medical officer of health) points out that this low death rate was to a great extent due to the meteorological conditions which prevailed during the greater part of the year and not to circumstances dependent upon the amount of attention which the council chose to bestow upon the state of its district For some years past the Local Government Board has been urging upon the district council the desirability of increasing the staff of sanitary inspectors employed in the two valleys but the council still refuses to act upon the advice of the Board The six inspectors who are employed are expected to act as building inspectors and to inspect the laying of all new drains in addition to the specific duties laid down by the Local Government Board The amount of work to be done by these officials may be gathered from the statement that there are nearly 1000 workshops in the district and that last year they investigated and reported upon 1542 cases of infectious disease and disinfected over 1200 houses. Dr. Jenkins very properly suggests that some of their duties should be undertaken by other officials. The rainfall at the head of the great valley in 1903 was 113 inches and about the middle of the same valley it was 94 inches. With a knowledge of this very large amount of rain falling in the district it is at first a little startling to read that the most pressing need of the locality is the provision of a more abundant supply of water. It appears, however, that although for the inhabitants of one portion of the two valleys there is ample water storage, amounting to 200,000,000 gallons, there is for a population of about 60,000 persons in the great valley storage equal to only 8 days' supply, even when reckoning the daily consumption at 14 gallons per head—a very small amount when it is remembered that water carriage of excreta is universally adopted in the Rhondda valleys. The district council is to be commended for having provided a refuse destructor, which, however, only destroys 16 tons out of the 200 tons of refuse which have to be dealt with each day. An enormous quantity of household refuse is deposited on "tips," many of which are quite close to dwelling-houses.

Death of Mr. Donald Fludyer Boulton, M.R.C.S. Eng., L.S.A.

Through the death of Mr. D. F. Boulton a prominent figure has been removed from the social life of the town of Usk. About three weeks ago Mr. Boulton had an apoplectic seizure to which he succumbed on Sept. 18th. He was born in the year 1842 and received his medical education at St. Bartholomew's Hospital. Soon after qualifying he joined his father in practice in Usk, where for more than 30 years he was surgeon to the prison. As a judge of horseflesh and a straight rider Mr. Boulton was well known for many miles around Usk and he had the instincts of a true sportsman. He leaves a widow and daughters.

Bristol General Hospital.

At the half-yearly board meeting of the subscribers to the Bristol General Hospital, held on Sept. 12th, the president (Mr. Proctor Baker) expressed regret that the general subscriptions did not increase but spoke in warm terms of the growing support given by the working classes. Mr. Baker added that about £1000 must be spent on improving the isolation buildings and that the committee must soon add a new wing to the institution.

SCOTLAND.

(From our own Correspondent.)

New General and District Hospitals, Glasgow.

The new General Hospital situated at Stobhill and the two district hospitals at Duke-street and Oakbank, as well as the new Nurses' Home at Woodilee Asylum, Lenzie—all erected and equipped by the parish council of Glasgow and the Lunacy District Board—were formally opened on Sept. 15th. The company, consisting of about 100 gentlemen, who took part in the proceedings drove from the Parish Council Chambers to the Stobhill Hospital. There they assembled on the lawn in front of the administrative block and Mr. George Dott, chairman of the parish council, in a short speech declared the three hospitals open. He referred to the simplicity in structure of the buildings, there being no ornamentation or decoration. The policy of the council, he said, had been to get the largest accommodation with the best equipment at a minimum cost and he thought that it had succeeded. After a short dedicatory service some time was spent in inspecting the buildings. The company next drove to Woodilee Asylum and took part in a similar function in connexion with the opening of the Nurses' Home recently erected there. The aim that the parish council has had in view in erecting the general and district hospitals is to permit of the dissociation of the ordinary poorhouse cases from those requiring active hospital treatment. The buildings at Stobhill, situated to the north-east of Springburn Park, are erected for the accommodation of the infirm class of poor and also children, while the district hospitals situated in Duke-street and at Oakbank, near Garscube Toll, will be reserved for acute cases. The Stobhill Hospital provides accommodation for 1650 patients, 100 nurses, and 70 servants. Houses are also provided for 20 workmen. The site extends to 54 acres and cost £8300, while the buildings, consisting of brick with stone lintels and sills, cost £299,836. The hospital consists of the following sections:—14 medical and surgical wards, four wards for aged and infirm inmates, one isolation block, 13 children's wards, nurses' home, medical officer's house, accommodation for officials, administrative block, laundry, mortuary, and gate lodge. The Duke-street, or Eastern District, Hospital will accommodate altogether 244 patients, 133 male and 111 female. In the male section there will be beds for 72 medical cases, 25 surgical cases, and seven skin cases; in the female section there will be provision for 36 medical cases, 25 surgical cases, ten children, seven skin cases, and four maternity cases. There will be also two wards for 44 mental cases, 22 male and 22 female. In addition there are in two blocks wards for probationary and isolation cases, a well-equipped operating theatre, mortuary, post-mortem room, and pathological laboratory; also a block in which are placed the administrative department and accommodation for 30 nurses and 12 other members of the staff. Owing to the limited space at disposal the architect had to adopt the plan of having the wards radiating from a common centre, thereby gaining the maximum of air space round each block. The site covers an area of 8429 square yards, while the cost of the buildings amounted to £75,006. The Oakbank, or Western District, Hospital consists of eight blocks built in a parallel series. The ward pavilions provide accommodation for 207 patients. The administrative department occupies a convenient position in the middle of the frontage. The receiving block contains male and female wards of three beds each. The surgical pavilion of two storeys contains two wards of 17 beds each and two of four beds each, the latter for septic and aseptic cases; also a well equipped operating theatre. The medical block has 12 wards—six with 15 beds each, four with three beds each, two isolation wards with two beds each, and six side rooms with one bed each. There is also provision for maternity cases and skin cases. There is accommodation in the nurses' home, which readily communicates with the different pavilions, for 34 nurses. The site covers an area of 7198 square yards, and the buildings, which are of brick, cost £71,530.

Enteric Fever in Navan.

At a meeting of the Navan urban council held on Sept. 15th a letter was read from the Local Government Board forwarding the report of its medical inspector, Mr. D. Edgar Flinn, on an outbreak of enteric fever which has recently occurred in the town. The inspector stated that during the month of August 11 cases—all confined practically to one area—had been notified. The sanitary condition of that area was unsatisfactory and the construction of a new sewer and the closure of a dangerous well were advised. It is reported that there are 14 cases at present under treatment and that three deaths have occurred.

Small-pox on the Arran Islands.

Some excitement has been caused in the city of Galway by the fact that small-pox has recently appeared on the Arran Islands situated near the mouth of Galway Bay. They are not far removed and there is daily communication between the islands and the mainland. The intercepting hospital in Galway has been renovated to prepare for any emergency. At the last weekly meeting of the Galway board of guardians Sir Acheson MacCullagh, Local Government Board inspector, requested the members present to make all arrangements possible in order to stay the spread of the disease. An old disused schoolhouse is to be transformed into a hospital and tents are being provided for nurses. The Rev. Father Farragher, the parish priest of the island, has contracted the disease and the islanders have refused to send their children to be vaccinated by the resident medical officer who is in attendance on him. The relieving officer has telegraphed and a second medical man is about to be sent by the Local Government Board.

Rainfall in Belfast.

In the month of August rain fell on 30 days to the amount of 4·90 inches, making the total for the year 25·68 inches. The average amount for the period in question is 4·26 inches.

The Milk supply of Belfast

For some time past a correspondence has been going on in one of the Belfast daily newspapers on the question of the milk supply of the city One writer, who is evidently opposed to anything like the municipal supply of sterilised milk, recommends that in the production of milk, in its carriage, and in its distribution methods should be adopted which would eventuate in its being supplied to the householders pure and not requiring any subsequent home treatment

Scarlet Fever in Newtownards

At a special meeting of the urban council of Newtownards, co Down, held in the town hall on Sept 17th, a report was received from Mr David Jamison, medical officer of health, to the effect that the epidemic of scarlet fever was not abating as 13 cases had arisen since Sept 7th making a total of 55 this year as compared with 25 in 1903 Mr Jamison recommended the closing of day schools and Sunday schools for a time and the boiling of milk It was decided to close the schools for four weeks There are 31 cases in hospital

Fees of Dispensary Medical Officers

The Local Government Board has written to the Glenties Board of guardians to the effect that if the guardians do not pay Dr T McDonald, who is acting as locum tenent in the place of the dispensary medical officer of Ardara, a remuneration of £3 3s per week for the month the Local Government Board will feel obliged to direct payment at that rate, it also requested the guardians to reconsider the question of the remuneration of the practitioner who acted as temporary medical officer of the Killybegs dispensary district in May The guardians decided to adhere to their original resolution on the matter to pay a lower fee stating that they saw no reason for the interference of the Local Government Board, seeing that the medical officers were satisfied

Small pox in Monaghan

At a meeting of the Monaghan rural district council on Sept 19th a case of small pox was reported in Dr J Henry's district at Drumhillagh

Sept 20th

NEW YORK

(FROM OUR OWN CORRESPONDENT)

A National Quarantine

THERE is a growing belief among the more advanced sanitary authorities of this country that the old and often very impracticable State quarantine system that has existed from the foundation of the General Government must be superseded by a well organised national quarantine under the sole direction of the Public Health and Marine Hospital Service The quarantine laws of the several States are crude and generally inefficient and at the same time incompatible with each other Such laws are often found to be seriously and unnecessarily obstructive of commerce and travel Another feature of the argument in favour of general laws and regulations governing quarantine and a central power managing them has lately been brought forward by the Government of the Republic of Mexico The quarantine of Texas is acting within its rights and duties to protect the people from yellow fever, but *it is contended* that the rules which it prescribed for that purpose were altogether too restrictive The Government of Mexico can make no appeal to our Government for the power to make quarantine regulations for the ports of Texas are conceded by the United States to Texas The agitation which this event is exciting *tends powerfully to strengthen the position of* the advocates of a national quarantine There is a prospect of an effort to secure the enactment of a law by the next congress creating a national system of quarantine laws and placing the management of the quarantines established by such legislation under the control of the Public Health and Marine Hospital Service

Revenue Laws affecting Physicians

The Collector of Internal Revenue has received instructions to the effect that a practising physician who without holding the special tax stamp of a retail dealer in liquors under the United States Internal Revenue laws furnishes his patients with distilled spirits, wine or malt liquors under conditions constituting sales of these liquors directly or indirectly, involves himself in liability to criminal prosecution under these laws unless he shows that the liquors thus furnished have been compounded into medicines by the addition of some drug or medicinal ingredient If the liquors are not so compounded into medicines by the addition of some drug he cannot sell them, even for medicinal purposes without involving himself in special tax liability

A National Association for the Study of Tuberculosis

This association is formed for the purpose of making an exhaustive study of tuberculosis and the best methods of prevention It is a culmination of the efforts that have been made during the past two or three years to combine the work of many societies in one effective organisation, fully equipped to cover the whole field of investigation Its chief office will be in New York There is no intention of *founding any sanatorium or dispensary for the treatment* of the disease The work planned for the present is the collection and dissemination of information of every kind bearing on the disease The association will constantly aim to encourage local authorities to adopt measures for the prevention of the spread of tuberculosis by giving them desired information and in this respect its office will be a centre of collected facts relating to every phase of the prevention of this disease Its first work will be the preparation of a directory containing exact and minute information regarding the 125 hospitals and sanatoriums in this country and Canada now devoted to the treatment of tuberculosis

Bedside Notes not Admissible in Evidence

The Supreme Court of New York holds that what are known as bedside notes are not admissible in evidence They were introduced into court during the examination of a hospital nurse who attended the plaintiff while a patient in the hospital She described the paper as a "temperature chart and said that such charts were used at the bedside of every patient for accuracy in recording symptoms Its contents related chiefly to the physical condition of the patient and specified particularly the injuries from which he was suffering The court stated that it was not aware of any rule of evidence which made such a paper, offered in such circumstances admissible

Pulmonary Tuberculosis among Street sweepers

Street cleaning Commissioner Woodbury of New York, himself a physician instituted an inquiry as to the prevalence of pulmonary tuberculosis in the corps of street-sweepers with important results Out of a total of 1872 men 283 were found to be afflicted with pulmonary complaints Of this number only 60 had tuberculosis The results of the investigation relieved the apprehensions of the men who became alarmed by the report of the physicians to the department who stated that more than 25 per cent of the men applying for sick leave had tuberculosis of the lung The low percentage of cases of tuberculosis among men who are constantly inhaling street dust in the city of New York *which on analysis has* been found to contain 62 per cent of filth of every description known in this city, was gratifying no less to the men than to the public

Sept 1st

FRAUDULENT VACCINATION CERTIFICATES —At the Old Bailey on Sept 14th Hugh Stanley Revell M R C S Eng L R C P Lond medical officer of the Wandsworth and Clapham Union who had pleaded guilty at the June Sessions of obtaining money from the guardians by means of fictitious charges for vaccination, surrendered *for judgment* The prosecution mentioned that the prisoner had defrayed the whole costs of the proceedings and the Recorder after mentioning that the prisoner had already been in custody for three months passed a nominal sentence which allowed him to be discharged The Recorder inquired whether the prisoner's name had been removed *from* the Medical Register and Mr Charles Mathews prisoner's counsel said that the General Medical Council was not at present sitting but that there was no doubt that the name would be removed

Obituary.

SURGEON-GENERAL JAMES JAMESON, M.D., C.B., K.H.S., LL.D.,

LATE DIRECTOR-GENERAL, ARMY MEDICAL SERVICE.

Surgeon-General Jameson was born at Kilburnie, Ayrshire, on August 15th, 1837. He graduated M.D. at the University of Glasgow in 1857 and entered the Army Medical Department in the same year, being gazetted Staff assistant surgeon on Nov. 9th. He was ordered to Canada in January, 1858, and he served for nearly 11 years in various stations of British North America, including Nova Scotia. During that period he was appointed, in 1862, assistant surgeon of the 47th (now the 1st Battalion "Loyal North Lancashire") Regiment and he followed the fortunes of that corps until his promotion. The regiment was ordered to the West Indies in December, 1868, and it was Assistant Surgeon Jameson's lot to proceed to Trinidad in medical charge of a detachment. Here, in 1869, he made acquaintance with tropical disease of virulent form—he had an opportunity, of which he availed himself, of showing his zeal, energy, and assiduity in the performance of his professional duties and he was rewarded by special promotion to the rank of staff surgeon "in consideration of his highly meritorious services during the epidemic of yellow fever at Trinidad." This promotion removed him from the regiment, in which he was a great favourite of both officers and men. Returning to England in May, 1870, he remained at home but a few weeks when he volunteered for service with the English ambulance in France during the Franco-Prussian war and he commanded a division thereof during 1870–71. It so happened that most of his time was spent in the company of the Prussian invading forces and not very long before the close of his service as Director-General he received the Emperor William commemoration war medal, by special act of grace conferred upon him by the German Emperor. At the conclusion of the war Staff Surgeon Jameson proceeded to the Bahamas where he served until 1875. Returning home for four or five years his next foreign service was in India, the Madras Presidency, where he remained from 1881 to 1886. During a portion of this time he was in medical charge of the 12th Lancers. We have received from a former officer of that regiment an appreciation which may well be given in his own words:—

"Poor Jameson was in medical charge of the 12th Lancers from their arrival in Bangalore in 1882 and was the first *non-regimental* medical officer that we had to do with. We very soon learned to appreciate his value. Professionally and socially he was found to be admirable, and among all ranks and among the families of officers, non-commissioned officers, and men, he was recognised as a true friend. He was infinitely kind and attentive, never sparing himself in any way when he could be of service to anyone. It was of enormous importance to us all to feel that we had at hand a medical adviser so tender in his ways and in whom we had such complete confidence. And he was always the best and most genial of comrades; an excellent sportsman—full of sympathy with every manly pursuit. He was everything that a man in his position should be—respected, loved, and implicitly trusted."

He attained the rank of Deputy Surgeon-General (subsequently changed to "Surgeon-Colonel") in September, 1888, his first service in an administrative capacity being as principal medical officer on the staff of General Lord Frankfort in Egypt, during the years 1889 to 1893, where, in the words of the general, "he rendered excellent service."

In 1893 he was promoted Surgeon-Major-General and became "personal assistant" (the post being that now known as Deputy Director-General) to the then head of the department, Sir William MacKinnon, K.C.B., whom he eventually succeeded on May 7th, 1896. He received a meritorious service reward in October, 1896, was decorated C.B. in 1897, and in the same year was appointed honorary surgeon to Queen Victoria.

Then came the "troublous times" of the Boer war. As head of the Army Medical Service he was responsible for the medical and sanitary arrangements of a campaign which attained dimensions far beyond the calculations of everyone—including those supposed to be "in the know." It must be in the recollection of all that a Royal Commission was appointed to make inquiry and to report upon the "Care and Treatment of the Sick and Wounded." The opinion of that Royal Commission was "that in no campaign have the sick and wounded been so well looked after as they have in this." Bearing in mind that at the outbreak of the war the establishment of the Royal Army Medical Corps was not even equal to peace requirements (it was "practically exhausted in supplying the First Army Corps and in manning the base hospitals") the sudden and long-continued "expansion" which became necessary was no easy matter. But Director-General Jameson "tackled" the difficulties with characteristic energy, and the verdict of the tribunal was one in which he was entitled to feel legitimate pride.

It is impossible for us to account for the fact that his strenuous efforts received no official recognition. There must have been some extraordinary misunderstanding or misconception of the character of the man who worked so loyally for his Sovereign and for the good of the service. Not only was his name absent from the Honours Lists, but he was requested to retire from his post after the completion of five years' tenure, it being understood that it was to be held by him for seven years (for a rule recently promulgated was not supposed to apply to him, but to his successors). For this premature dismissal no very satisfactory reason was forthcoming, the only plausible explanation being that reorganisation and reconstruction of the medical service were "in the air" and the authorities wished for "a new broom." This would have been better understood had the enforced retirement been carried out generously and gracefully, but the omission of all recognition came as a grievous disappointment, not only to the corps of which he was the popular chief, but to the whole body of the medical profession—to say nothing of his friends. The profession, however, hastened to do him honour by inviting him to a complimentary banquet on July 24th, 1901, which was presided over by Sir William Church, Bart., President of the Royal College of Physicians of London (who, it will be remembered, was a member of the Royal Commission).[1] He also received honorary degrees from three or four universities. It should not be forgotten that it was during his term of office that the Army Medical Department was converted into the "Royal Army Medical Corps" and substantive rank was introduced. As regards his personal character he was conspicuous for his loyalty to his officers and profession. Those who worked with him were struck with his thorough honesty, his generous confidence in all who served under him, and his ability to take a sound, commonsense view of any question which had to be considered. He had a keen sense of humour withal and was always "excellent company."

Surgeon-General Jameson married in 1864 a daughter of the Rev. R. W. Cartwright of Kingston, Ontario, who survives him, together with five sons and one daughter. Four of his sons are medical men, one being in the Royal Navy, two in the Royal Army Medical Corps, and one in private practice. The announcement of his death came as a shock to all who knew him, for he always appeared to be the embodiment of sound health and vigour. He had quite recently been to Norway on a fishing expedition and apparently he must have overtaxed his strength by fatigue and exposure. Shortly after his return he had an attack of thrombosis in both extremities and just when recovery was confidently expected embolism supervened followed by septic pneumonia. Death occurred at his house at Eltham on Sept. 13th. The funeral took place on Sept. 17th at Greenwich cemetery and was largely attended by relatives and friends, amongst whom were some of his old comrades of the 47th Regiment. The Director-General was represented by Surgeon-General A. H. Keogh, C.B., Deputy Director-General (Sir William Taylor being absent in South Africa), and his staff at the army medical office, and there were present several officers on the retired list as well as many now serving in the Royal Army Medical Corps. There was also a strong company of the Royal Army Medical Corps from the Herbert Hospital. The coffin was borne on a gun carriage provided by the Royal Horse Artillery who also furnished the firing party.

WILLIAM LEE DICKINSON, M.D. CANTAB., F.R.C.P. LOND.,

SENIOR ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL.

A GREAT calamity has fallen on St. George's Hospital and School by the sudden death of Dr. Lee Dickinson, senior assistant physician, at the early age of 40 years. The closing

---

[1] A report of the proceedings at this dinner appeared in THE LANCET of July 27th, 1901, p. 247.

SURGEON-GENERAL JAMES JAMESON, M.D., C.B., K.H.S., LL.D.

of a career which had performed so much good work for St George's and which promised so much more for medical science and for the public service must not be allowed to pass without some attempt to show how Dickinson was regarded by his friends and colleagues To the general public he was, perhaps, less known than men of his age usually are, for he was of a most retiring disposition Yet he had done enough to show what there was in him and he was well known at the various societies as one of the most rising of our younger physicians and pathologists Dr Lee Dickinson was the son of Dr W H Dickinson and the grandson of Dr James Arthur Wilson once well known as physician to St George's Hospital His education, both general and professional, was received at Winchester, at Caius College Cambridge, and at St George's Hospital He took the diplomas of M R C S Eng and of M R C P Lond in 1886 and 1889 respectively and in 1894 he was elected F R C P Lond In 1890 he took his degree of M B at Cambridge proceeding to M D in 1893

At an early period in his career he joined the medical staff of the school of St George's Hospital, of which his father is so distinguished a member He also held for five years the position of assistant physician to the Hospital for Sick Children in Great Ormond street resigning it when in February, 1894, he became assistant physician to St George's Hospital with the unanimous support of the whole staff He worked hard at the school and was looked on as one of the most valuable members of the teaching body, nor would he ever spare himself from duty, though he soon began to show symptoms of the complaint which has so early laid him low He became lecturer on medical jurisprudence and toxicology and much of his work was connected with the latter subject He was the author, or joint author, of several papers of value in the Proceedings of the Royal Society and the Transactions of the Clinical Society He was a successful lecturer and much esteemed as a clinical teacher He was much thought of by his poor out-patients, to whom he was remarkably kind and considerate As definite proofs of tuberculous mischief became evident he found himself obliged to request a change of climate and a period of repose Accordingly he obtained from the board of governors leave of absence for half a year and repaired to South Africa in the year 1898, where he lived in the neighbourhood of Harrismith with so great benefit to his health that many of his friends wished him to settle in

own what

sk rather

he loved

and his prospects of distinction in the practice of the art which he loved still more At first his resolution seemed to be justified His health improved and he was able to discharge his duties both at St George's and at the branch hospital at Wimbledon with the exact punctuality which seemed a part of his nature He was indeed the very model of a hospital physician, skilful in diagnosis, ready in practice lucid in teaching, kind and good to the patients unselfish in his devotion to duty, and by his fine powers of observation fitted to carry on the practice of his art to yet higher perfection

the thin spun life

So was it with him His friends had lately remarked that he seemed to grow more haggard and distressed but he made light of any foreboding and protested that he was well Indeed he seemed to become stronger and better at his father's house at Tintagel in Cornwall, until on Sept 6th without any warning, a sudden and overwhelming fit of hæmoptysis carried him off in a few minutes

So died a man of whom it may be truly said that no one knew how good he was, since he had not had the opportunity to show it It is not necessary here even to allude to the household virtues of the deceased His death will long be mourned by his family and his many friends

---

SAMUEL JOHN HUTCHINSON, M R C S ENG, L D S

WE regret to announce the death on Sept 15th, at the age of 56 years of Mr Samuel John Hutchinson He came of an old Quaker family and was born at Helmsley in Yorkshire His early education was obtained at a local school and he subsequently came to London to study medicine and pursued his studies at University and King's College Hospitals and the Royal Dental Hospital In 1872 he obtained the diploma of Licentiate of Dental Surgery of the Royal College of Surgeons of England and two years subsequently he became a Member of that College He practised dental surgery and during his whole career took a keen interest in all that appertained to the advancement and welfare of that branch of medicine At the Royal Dental Hospital where he was one of the early students, he held the position of assistant surgeon and surgeon for 11 years resigning his appointment on being elected to the lectureship on dental surgery and pathology—a post that he resigned on his appointment as examiner in dental surgery to the Royal College of Surgeons of England He was at the time of his death consulting dental surgeon to the National Dental Hospital and University College Hospital He took an active part in the work of the Odontological Society of Great Britain and held in succession the offices of honorary secretary curator, president and treasurer To the British Dental Association he devoted much of his spare time and held for several years the office of president of the representative board He occupied the office of president of the association when the annual general meeting was held in London in 1901 At the time of his death he was one of the trustees of the Benevolent Fund His life was in all respects an active one and it is possible that the strain of a busy practice combined with his many other duties may have told severely on his health He died at his residence "Ford," Branksome Park, Bournemouth and was buried on Sept 20th at Hampstead cemetery

---

DEATHS OF EMINENT FOREIGN MEDICAL MEN —The deaths of the following eminent foreign medical men are announced —Dr Anton Drasche extraordinary professor of medicine in Vienna and editor of the great 'Bibliothek der gesamten Medicinischen Wissenschaften'—Dr Hygino de Sousa, assistant professor of ophthalmology in the Lisbon Faculty of Medicine —Dr Albert Landerer, surgeon to the Schonberg Hospital Berlin and until recently chief surgeon to the Karl Olga Hospital Stuttgart Dr Franz Riegel, professor of medicine in Giessen and one of the most able clinical physician in Germany His name is specially associated with the recognition of the importance of the determination of hydrochloric acid in cancer of the stomach

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE —*Bologna* Dr R Lambrinzi has been recognised as *privat docent* of Psychiatry and I Pathological Anatom younger brother of P on whom the Universi honorary degree has succeeding Dr Gaffky —*Grat* Dr Rudolf Muller has been recognised as *privat docent* of Pharmacology and Pharma cognosis and Dr Albert Blaschek as *privat docent* of Ophthalmology —*Leyden* Dr E C van Leersum of Amsterdam has been appointed Professor of Materia Medica and Pharmacology —*Naples* Palermo has been appointed in succession to the late D (*College of Physicians and Surgeons*) Dr Janus R Hayden has been appointed Professor of Diseases of the Urinary System in succession to Dr Robert W Taylor resigned —*Padua* Dr Giuseppe N Sterzi has been recognised as *privat docent* of Anatomy Dr Rodolfo Schwarz as *privat-docent* of Operative Medicine, and Dr Saverio Spangaro as *privat docent* of External Pathology —*Pavia* Dr Adriano Valenti has been recognised as *privat docent* of Materia Medica and Pharmacology —*Pisa* Dr Giuseppe Carli has been recognised as *privat docent* of Internal Pathology and Dr Giulio Anzilotti and Dr Fernando Fabrini as *privat-docenten* of External Pathology, also Dr Francesco Pardi as *privat docent* of Anatomy —*Prague* (*Bohemian University*) Dr L Syllaba and Dr A Vesely, *privat-docenten* of Internal Medicine, have been granted the rank of Extraordinary Professors —*Rome* Dr D de Blasi has been recognised as *privat docent* of Bacteriology

Darlington Hospital and Dispensary.—The committee of the above has received an intimation from Sir Theodore Fry that Mr. Andrew Carnegie has promised to give at least £1000, required for the extension of the hospital buildings now almost completed. £6579 have been received for this special object in three years, and to place the committee in the position to claim Mr. Carnegie's offer it will be necessary to raise a further sum of at least £5000.

A Long-Deserved Punishment.—On Sept 14th Thomas Fisher, a butcher of Norwich, was sentenced at Clerkenwell police-court to six months' imprisonment for sending to Smithfield the carcass of a bullock which had died from tuberculosis. The offence had been committed two years ago, since when the prisoner had been in America. This is a notable example of the truth of

> Raro antecedentem scelestum
> Deseruit pede Poena claudo.

Small-pox and Vaccination.—A very severe epidemic of small-pox has lately been in progress at Dewsbury, the number of cases under treatment on Sept. 12th amounting to over 100. Since February about 300 cases have been admitted to the isolation hospital but some of these came from outside the borough. Many persons previously opposed to vaccination have submitted themselves to this simple operation, but in spite of medical advice the Northern Union Football League decided that the match, Dewsbury *versus* Leeds, should be played.

Trephining and Crime.—A Laffan telegram from Indianapolis dated Sept. 14th states that on May 7th an order was passed by the Juvenile Court permitting an operation to be performed upon an incorrigibly criminal boy, aged 16 years, whose mother stated that he had injured his head 12 years previously. A portion of the skull cap was found to be depressed and the bone was trephined. It was found to be thickened and to be pressing on the brain. The boy rapidly recovered and his mental and moral condition steadily improved. On Sept. 14th he entered the high school.

Water and the Sale of Milk.—A curious resolution was on the minutes of the sanitary committee of the Heaton Norris urban council at the meeting on Sept. 15th. The clerk was instructed to write to an estate agent to inform him "that unless a proper supply of water be provided to the farm premises within 14 days the tenant will be prosecuted for selling milk without being registered for the purpose." A good supply of clean water is, of course, necessary in any dairy farm for the cleansing of the cans and other vessels used, but the wording of the resolution is ambiguous.

Small-pox in a Workhouse.—A serious outbreak of small-pox has occurred in Ashton workhouse. Nine cases were reported there last week. Relieving officers have been instructed not to send paupers into the workhouse unless absolutely necessary. At a meeting of the board of guardians on Sept. 15th it was suggested that the source of infection was the borough small-pox hospital, "which was built right on the boundary of the workhouse," and that it should at once be removed. The workhouse committee was instructed to make an investigation. There is no mention of revaccination being carried out. The constant occurrence of these outbreaks of small-pox is not creditable to the country. It causes a large increase in the rates but probably that fact does not influence the faddists.

Colne and Holme Joint Isolation Hospitals.—The new isolation hospital of the Colne and Holme joint hospital district committee was opened recently by Mrs. Mallinson, wife of Mr. Thomas Mallinson, J.P., chairman of the committee, at Meltham Moor, near Meltham, about five miles from Huddersfield. The hospital district comprises 13 townships of the Colne and Holme valleys. The new hospital is for all infectious diseases except small-pox, for which provision had previously been made at Moor Top, Meltham. The total area of the land acquired for the site was 19 acres, of which about seven acres have been used for the hospital. The purchase price was £817 10*s*. and the entire cost of the hospital, including the site, amounts to about £19,000, which has been borrowed at 3½ per cent. The scheme was sanctioned by the West Riding County Council and the Local Government Board in March, 1902. The buildings comprise a porter's lodge, administrat block, isolation block, with two pavilions for scarlet fe patients and typhoid fever pavilion, and a laundry blo In all cases the standard of space fixed by the Local Gove ment Board has been complied with and all the buildi have a south-eastern aspect. Mr. Joseph Berry of Hudd field was the architect. A good supply of water has b obtained and is estimated at 4000 gallons a day an reservoir has been constructed with a capacity of ab 25,000 gallons. Mr. W. Crowther, J.P., who presided at opening proceedings, said that the population of the valleys was estimated in 1901 at 54,100 persons, the rate value was £190,000, and 1*d*. in the £ produced £ They had been assured that a rate of 2*d*. in the £ w suffice for the scheme, but it had already got to 4*d*., and without doing much actual hospital work.

Donations and Bequests.—By the will of M E. Peacock of Eccles £1000 have been left to the Hospital Sick Children, Pendlebury, Manchester, to endow a cot, £400 to the Home for Crippled Children, Manchester, similar purpose. The testatrix has also bequeathed £50 St. Mary's Hospital, Manchester; £1000 to the Ca Pavilion and Home, Manchester, to endow a cot; £50 the Northern Counties Hospital for Incurables; and £ upon trust to pay the income to a niece for life and after death to pay such sum to the Salford and Pendleton Hos and Dispensary.—The Royal Berkshire Hospital, the Su County Hospital (Guildford), the Aldershot Hospital, Alton Cottage Hospital, and the Basingstoke Cot Hospital will each receive £1000 under the will of Mr McDonald of Farnham.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institut and others possessing information suitable for this column, invited to forward to [illegible] *ected to the Editor, not later than* [illegible] *morning of week, such information* [illegible]

Daniell, G. W. Bampfylde, M.R.C.S., L.R.C.P. Lond., has appointed Anæsthetist to the Edinburgh Dental Hospital.

Felton, Walter B., L.R.C.P.I., L.R.C.S.I., has been appo Medical Officer and Public Vaccinator for the Newlyn East Di by the St. Columb (Cornwall) Board of Guardians.

Le Neven, vicar of Tavistock, William Turner, M.S. Lond., F.R.C.S., of 53, Queen Anne-street, Cavendish square, London, to Lily, only daughter of John Kerr Hamilton, of St. Rumon's, Tavistock.

DEATH.

BRANDT.—On the 19th September, at Royat (Puy de Dome), Annie, wife of Dr. G. H. Brandt, after a very short illness.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PAYMENT OF MEDICAL CERTIFICATES FOR ELEMENTARY SCHOOLS.

AT a recent meeting of the Northants education committee among other business a discussion took place about the payment of medical certificates. The following is the report of the proceedings given by the *Northampton Daily Chronicle* of Sept. 17th:—

> The elementary education committee reported the receipt of a resolution passed by the South Midland branch of the British Medical Association expressing the opinion that all medical certificates in cases where children are stated to be unfit to attend school should be paid for by the education authority; and also a communication on the same subject from the managers of the Wellingborough council schools. The present practice is to require the parent to prove that his child is unable to attend school. The committee were of opinion that this was a question of great importance and as such should be decided by the education committee.—Mr. Allebone moved that the medical certificates be not paid for by the committee. When tried at Earls Barton the number of certificates grew to such an extent and the expense became so large that ultimately that authority ceased to do so.—Mr. Rennie Wilkinson seconded.—The Chairman said almost all authorities required the parents to supply the medical certificates.—After further discussion it was decided to forward to the bodies who had forwarded resolutions on the subject copy of the resolution passed by the committee in March, requiring the parents to prove that the child is unable to attend, and stating that the committee saw no reason to vary their previous decision.

The question as to who should pay the medical man for giving a medical certificate concerning a child who is of school age has been many times debated and is a somewhat difficult one to answer. In our opinion the case stands thus. No medical man should be expected to spend his time, his skill, and his trouble in examining children and in giving a medical certificate as to their case without payment. The State compels all children of a certain age to attend school. The expenses of education are now for the most part borne by the ratepayers who are compelled by the State to contribute towards the expenses of education. It is manifestly to the advantage of the ratepayers that the health of children attending school should be looked after and as the State compels parents to send their children to school an compels the ratepayers of any given district to provide the necessary funds for education it seems to us that it is the duty of the State to see that the medical men by whose efforts epidemics may be frustrated should be paid and the persons who ought to pay them are manifestly not the parents of … ratepayers as a body. The … found by an increased rate … whether the money should come out of the taxes or out of the rates—does not seem important. On the whole, we think it would be fairer that the money should be paid by the taxes, for in that case the expenses would be more equally distributed over the whole country; but if the parents are made to pay it is most probable that in the majority of cases the medical … are the … be ill and … desired by a person …

PASTOR HOWTON AND DEMONIACAL POSSESSION.

THE *Morning Leader* of Sept. 7th contains an article "From Our Special Correspondent" which is headed "A Demon Hospital." It discusses what it calls the wonderful cures of Pastor Howton of Glossop and a portion of the article runs as follows:—

> There is to-day a boy in the Home who is a living testimony to the Pastor's almost uncanny system of "divine healing." This boy, whose name is Wycliffe ——, was taken on April 25th last to Dr. A—— of John-street, Manchester, who is a specialist in the diseases of children. Here is Pastor Howton's report of the case: "In the presence of myself and my wife and his father and mother this lad was very carefully examined by Dr. A——. He reported that the child was suffering from paralysis even to … of the tongue. His spine was dead half way up. 'All …
>
> … for this boy!' I obeyed the voice, and I will show the result." The pastor opened the door and shouted "Wycliffe!" A cheerful little voice answered the call and in another moment Wycliffe was in the room—a well set up boy of nine, with a clear eye and quite a healthy intelligence.

We were struck upon reading this report by certain discrepancies and we accordingly wrote to Dr. Henry Ashby of 13, John street,
